Abstract

We present *conditional random fields*, a framework for building probabilistic models to segment and label sequence data. Conditional random fields offer several advantages over hidden Markov models and stochastic grammars for such tasks, including the ability to relax strong independence assumptions made in those models. Conditional random fields also avoid a fundamental limitation of maximum entropy Markov models (MEMMs) and other discriminative Markov models based on directed graphical models which can be biased towards states

mize the joint likelihood of training examples. To define a joint probability over observation and label sequences, a generative model needs to enumerate all possible observation sequences, typically requiring a representation in which observations are task-appropriate atomic entities, such as words or nucleotides. In particular, it is not practical to represent multiple interacting features or long-range dependencies of the observations, since the inference problem for such models is intractable.

This difficulty is one of the main motivations for looking at conditional models as an alternative. A conditional model specifies the probabilities of possible label sequences given an observation sequence. Therefore it does not expend

Where we're going

- ▶ Flexible discriminative model for tagging tasks that can use arbitrary features of the input. Similar to logistic regression, but *structured*

...

HMMs, Formally

- ▶ HMMs are expressible as Bayes nets (factor graphs)

- ▶ This reflects the following decomposition:

$$P(\mathbf{y}, \mathbf{x}) = P(y_1)P(x_1|y_1)P(y_2|y_1)P(x_2|y_2)\dots$$

- ▶ Locally normalized model: each factor is a probability distribution that normalizes

Conditional Random Fields

- ▶ HMMs: $P(\mathbf{y}, \mathbf{x}) = P(y_1)P(x_1|y_1)P(y_2|y_1)P(x_2|y_2) \dots$
- ▶ CRFs: discriminative models with the following globally-normalized form:

$$P(\mathbf{y}|\mathbf{x}) = \frac{1}{Z} \prod_k \exp(\phi_k(\mathbf{x}, \mathbf{y}))$$

↑
any real-valued scoring function of its arguments

normalizer

- ▶ Special case: linear feature-based potentials $\phi_k(\mathbf{x}, \mathbf{y}) = w^\top f_k(\mathbf{x}, \mathbf{y})$

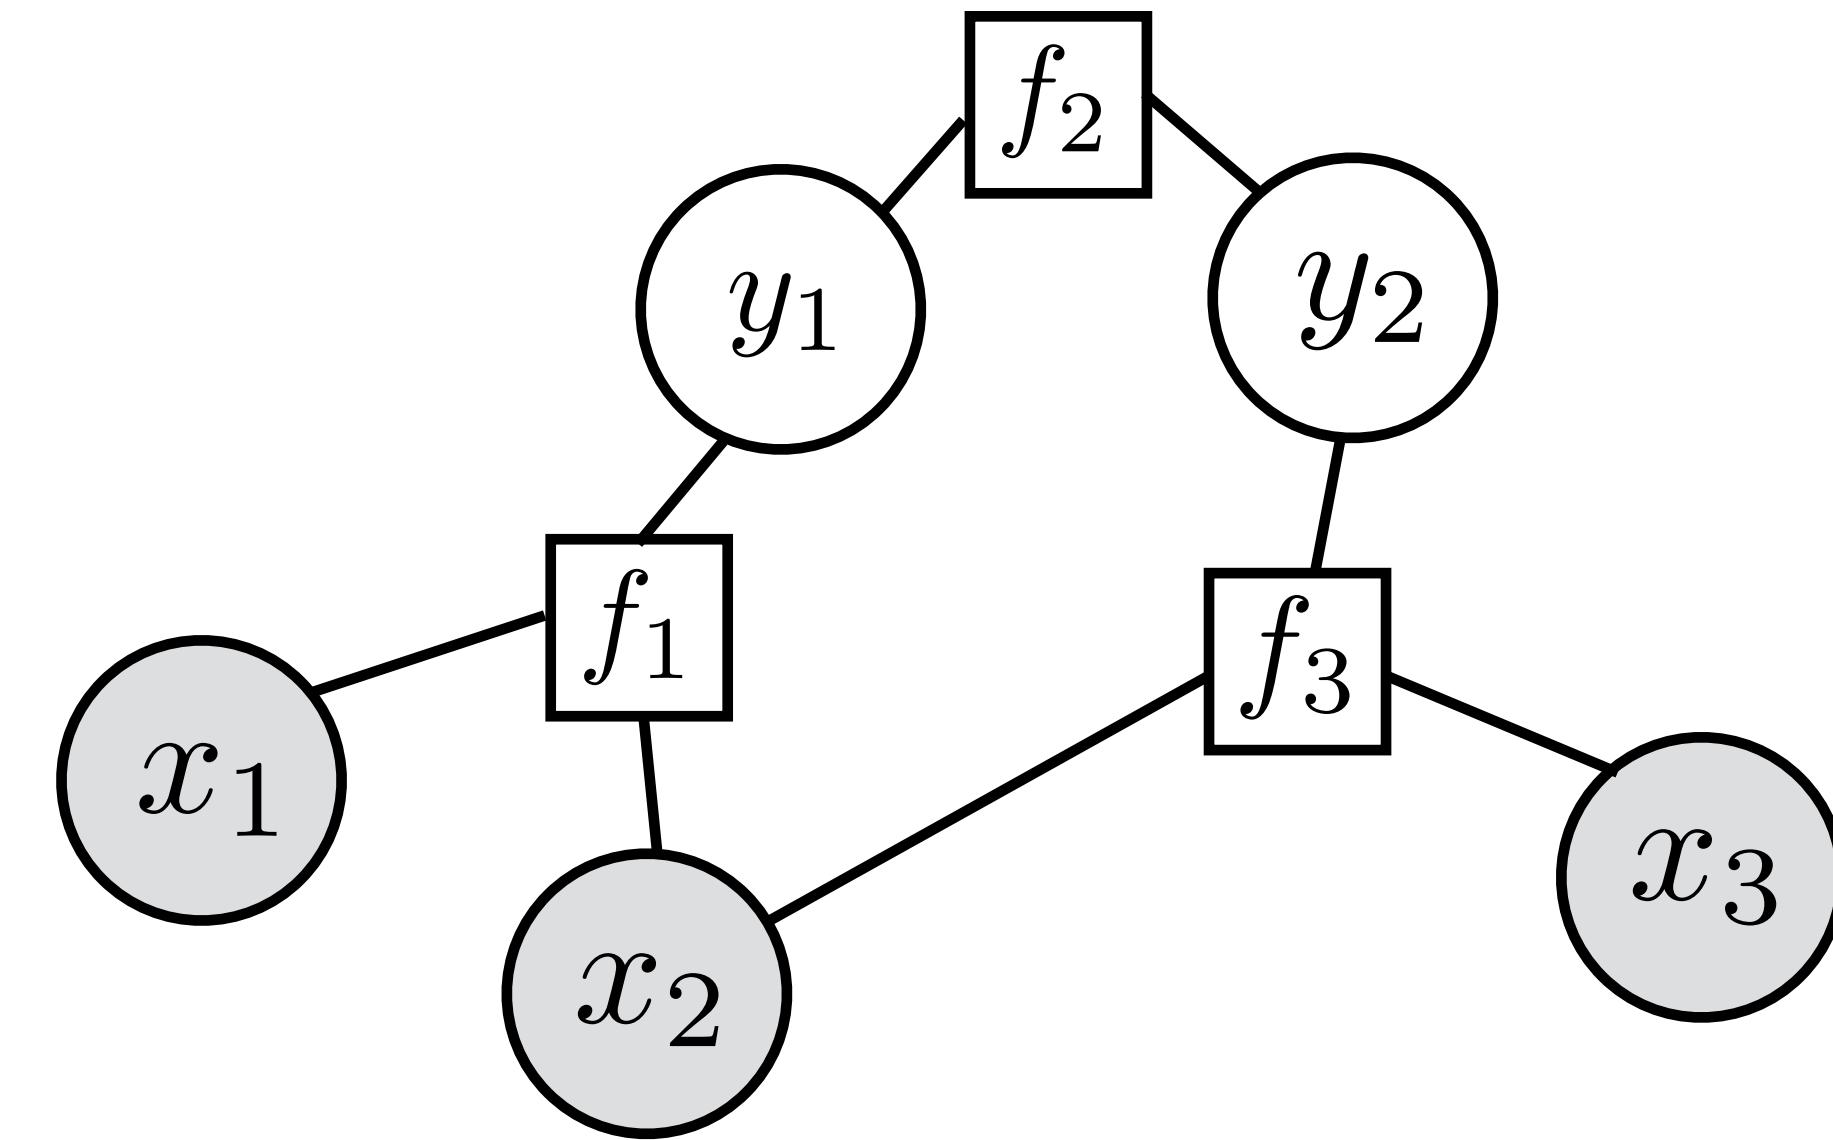

$$P(\mathbf{y}|\mathbf{x}) = \frac{1}{Z} \exp \left(\sum_{k=1}^n w^\top f_k(\mathbf{x}, \mathbf{y}) \right)$$

- ▶ Looks like our single weight vector multiclass logistic regression model

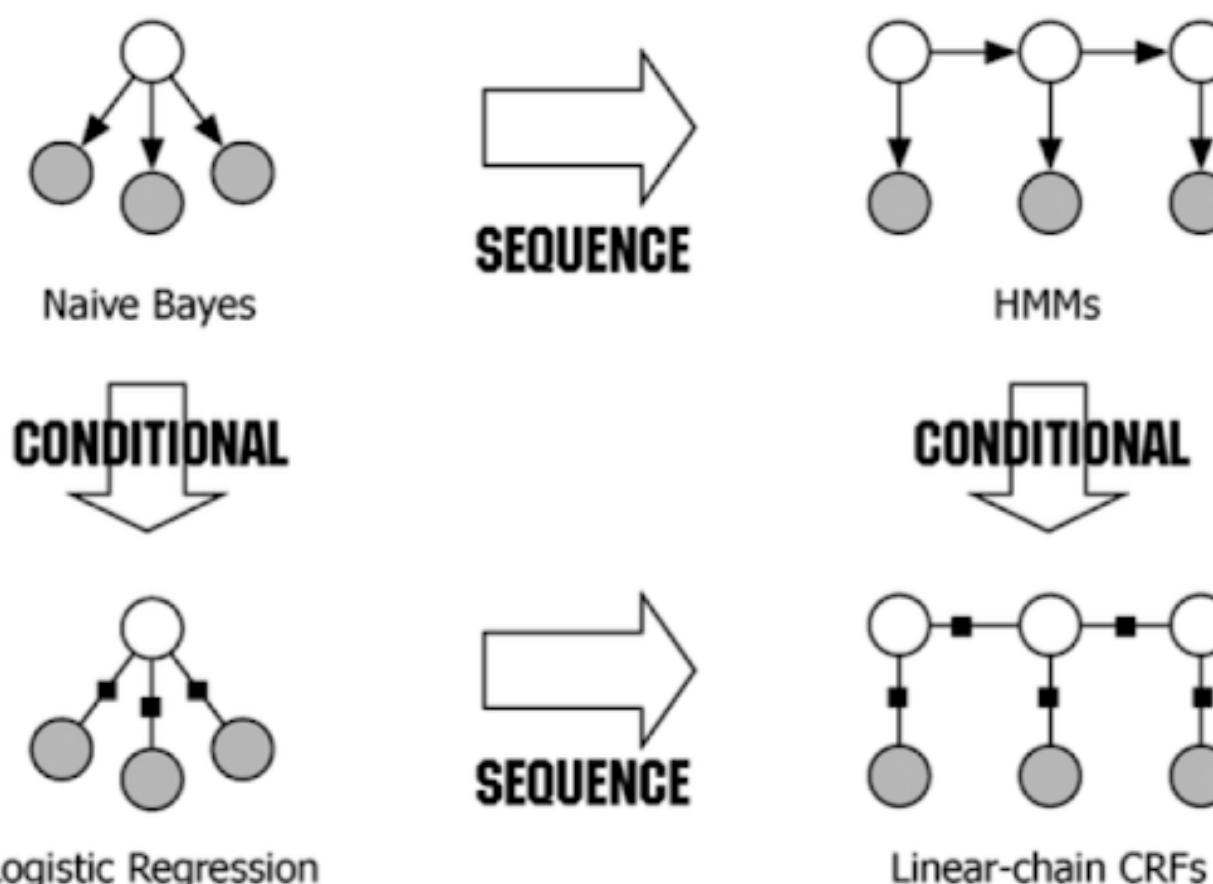

HMMs vs. CRFs

$$P(\mathbf{y}|\mathbf{x}) = \frac{1}{Z} \exp \left(\sum_{k=1}^n w^\top f_k(\mathbf{x}, \mathbf{y}) \right)$$

- ▶ Conditional model: x 's are observed
- ▶ Naive Bayes : logistic regression :: HMMs : CRFs
local vs. global normalization \leftrightarrow generative vs. discriminative

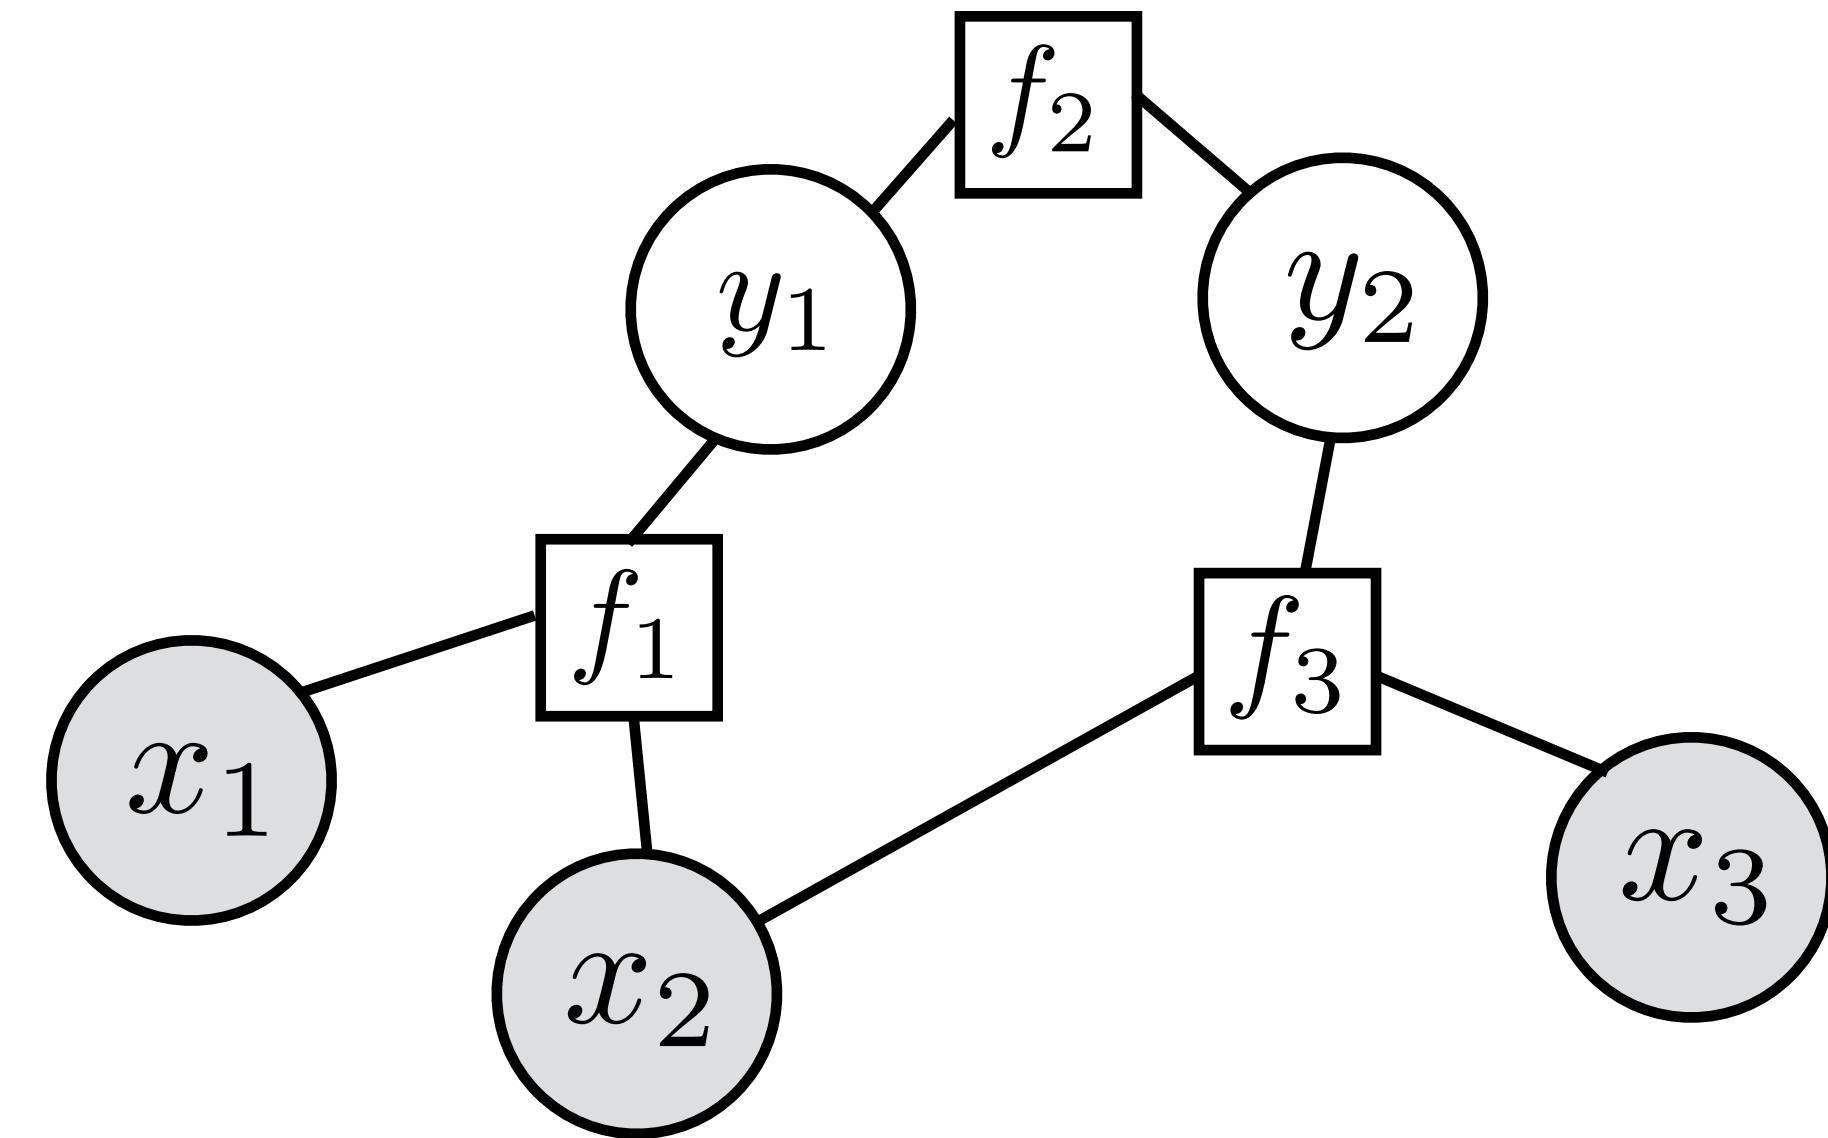

(locally normalized discriminative models do exist (MEMMs))

HMMs vs. CRFs

$$P(\mathbf{y}|\mathbf{x}) = \frac{1}{Z} \exp \left(\sum_{k=1}^n w^\top f_k(\mathbf{x}, \mathbf{y}) \right)$$

- ▶ Conditional model: \mathbf{x} 's are observed
- ▶ Naive Bayes : logistic regression :: HMMs : CRFs
local vs. global normalization \leftrightarrow generative vs. discriminative
(locally normalized discriminative models do exist (MEMMs))
- ▶ HMMs: in the standard setup, emissions consider one word at a time
- ▶ CRFs: features over many words simultaneously, non-independent features (e.g., suffixes and prefixes), doesn't have to be a generative model

Problem with CRFs

$$P(\mathbf{y}|\mathbf{x}) = \frac{1}{Z} \exp \left(\sum_{k=1}^n w^\top f_k(\mathbf{x}, \mathbf{y}) \right)$$

- ▶ Normalizing constant

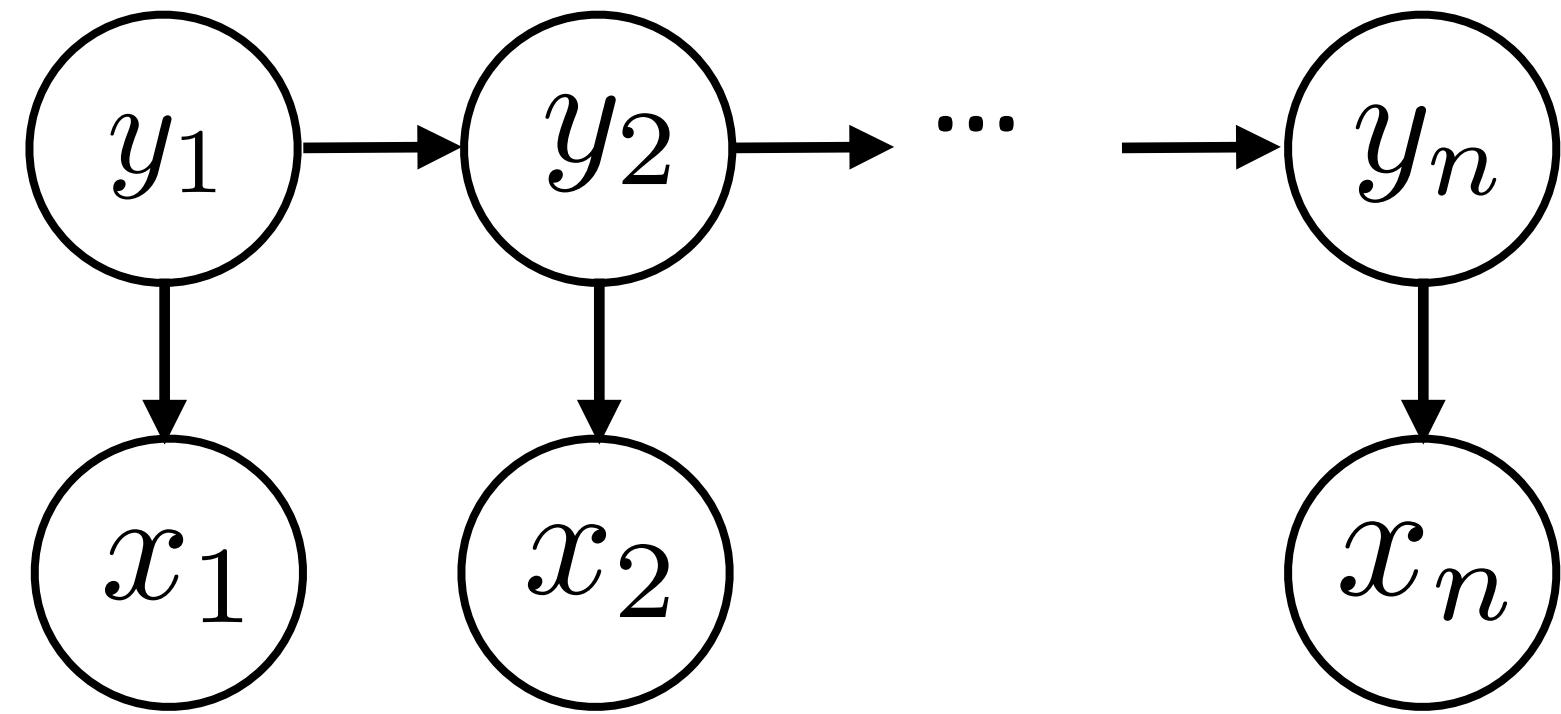

$$Z = \sum_{\mathbf{y}'} \exp \left(\sum_{k=1}^n w^\top f_k(\mathbf{x}, \mathbf{y}') \right)$$

- ▶ Inference: $\mathbf{y}_{\text{best}} = \operatorname{argmax}_{\mathbf{y}'} \exp \left(\sum_{k=1}^n w^\top f_k(\mathbf{x}, \mathbf{y}') \right)$

- ▶ If \mathbf{y} consists of 5 variables with 30 values each, how expensive are these?
- ▶ Need to constrain the form of our CRFs to make it tractable

Sequential CRFs

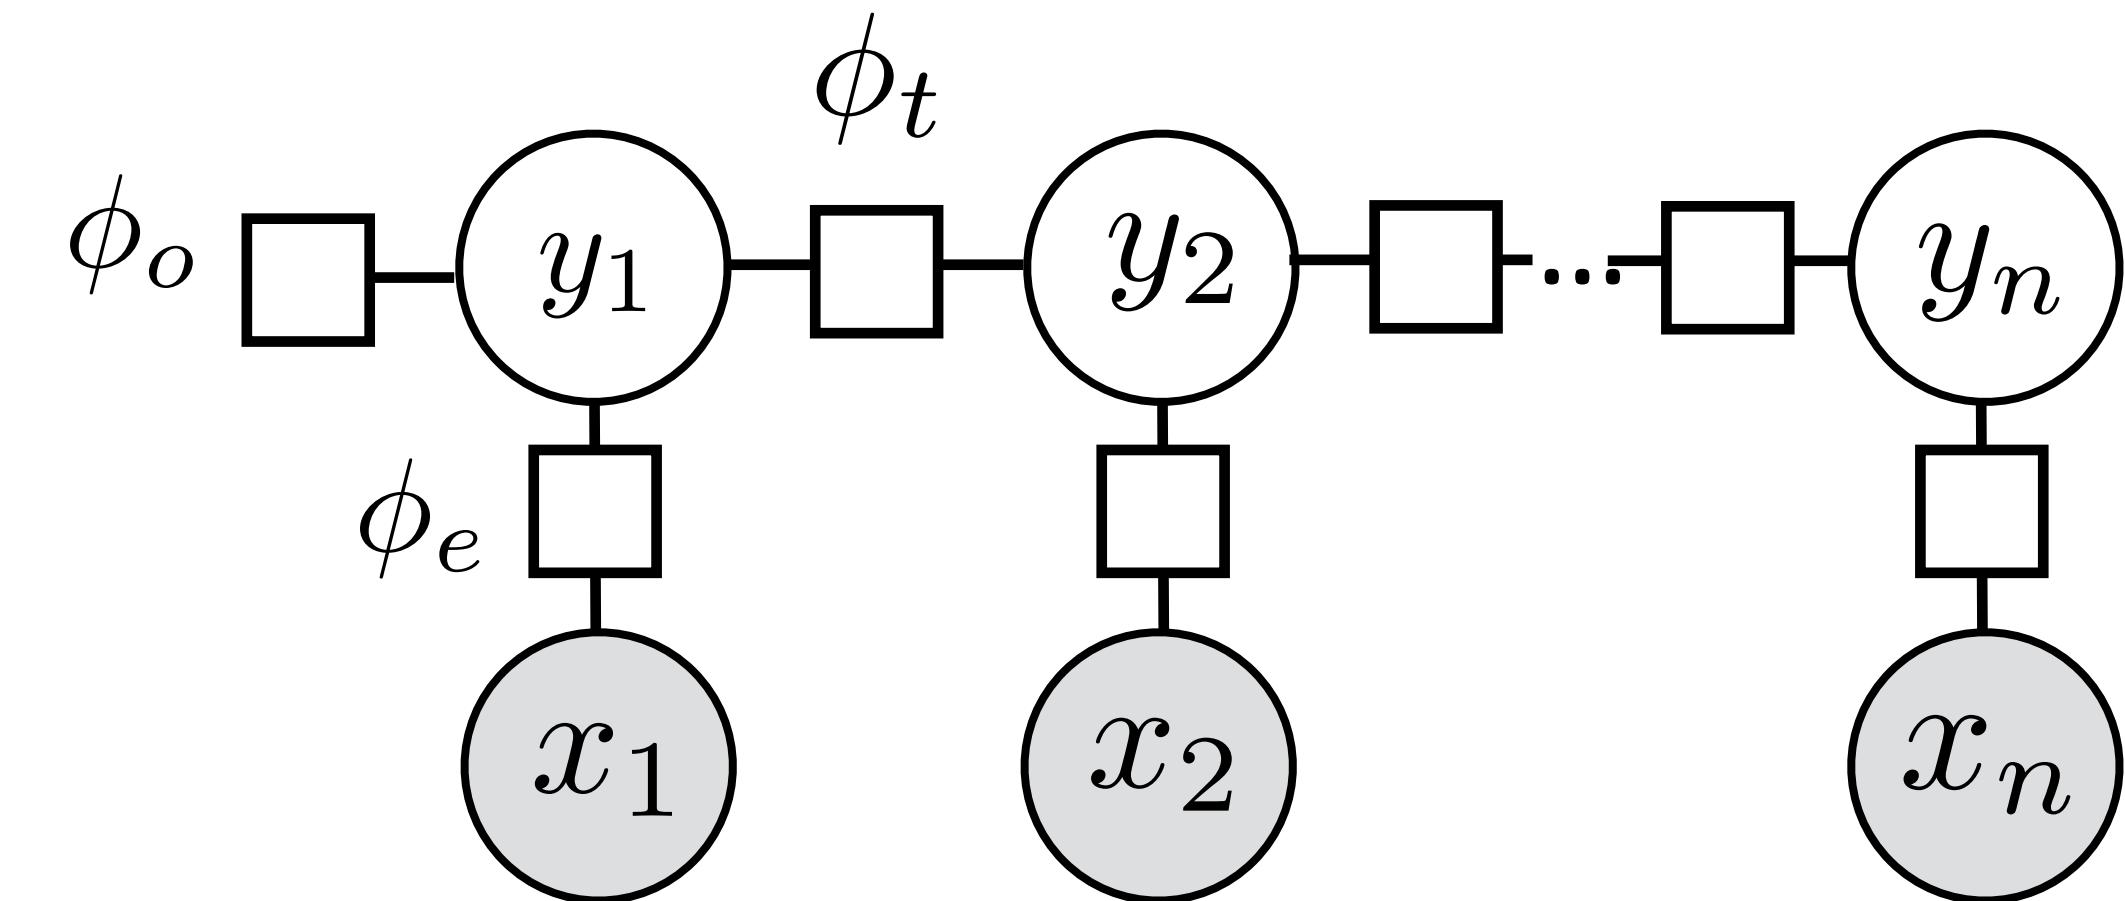

- ▶ HMMs: $P(\mathbf{y}, \mathbf{x}) = P(y_1)P(x_1|y_1)P(y_2|y_1)P(x_2|y_2) \dots$

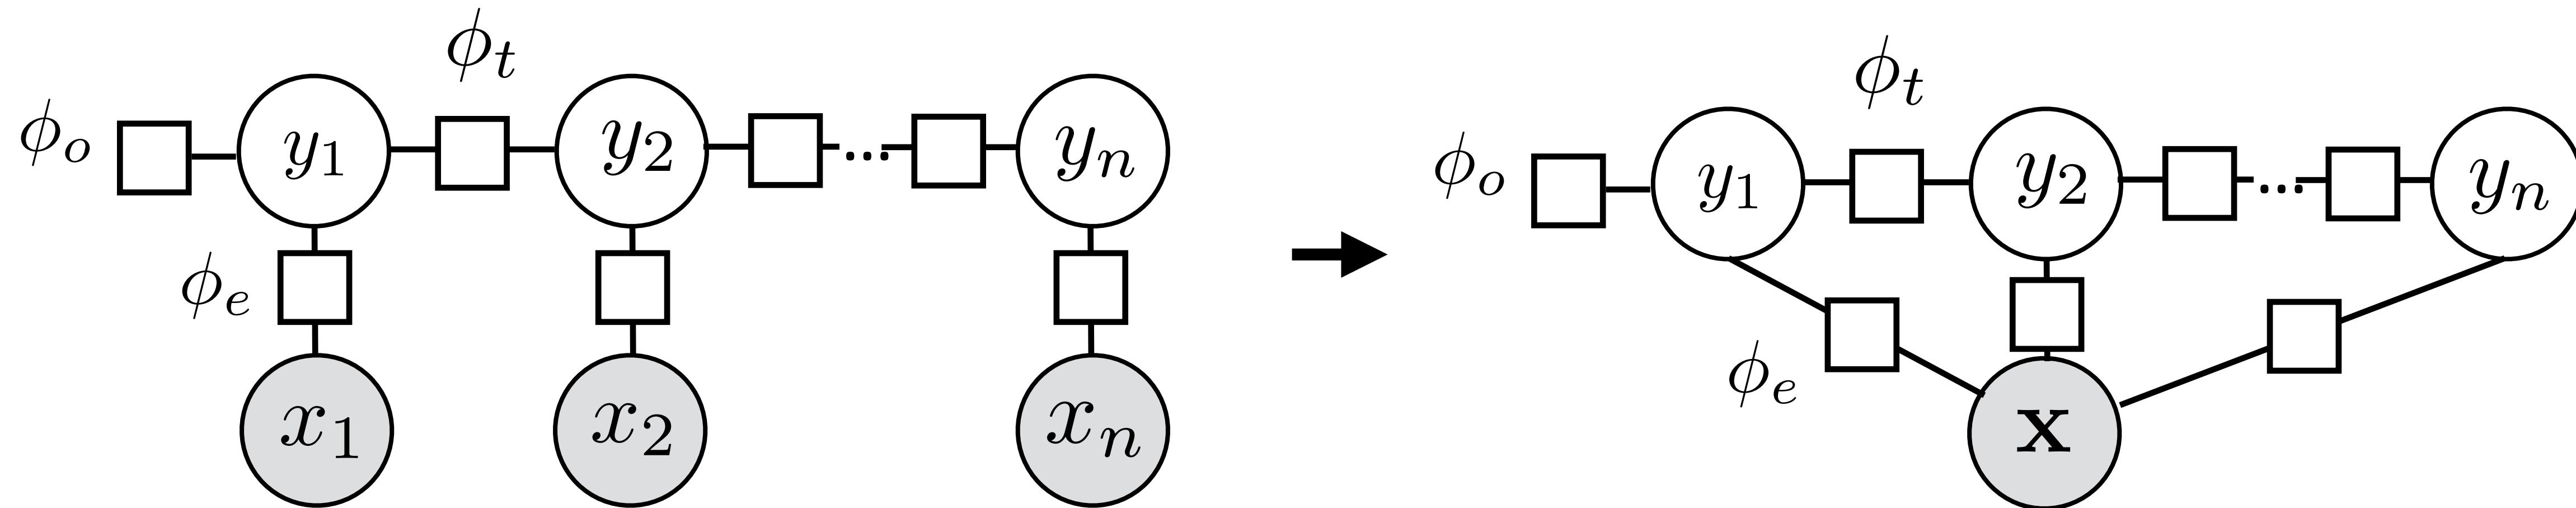

- ▶ CRFs:

$$P(\mathbf{y}|\mathbf{x}) \propto \prod_k \exp(\phi_k(\mathbf{x}, \mathbf{y}))$$

$$P(\mathbf{y}|\mathbf{x}) \propto \exp(\phi_o(y_1)) \prod_{i=2}^n \exp(\phi_t(y_{i-1}, y_i)) \prod_{i=1}^n \exp(\phi_e(x_i, y_i))$$

Sequential CRFs

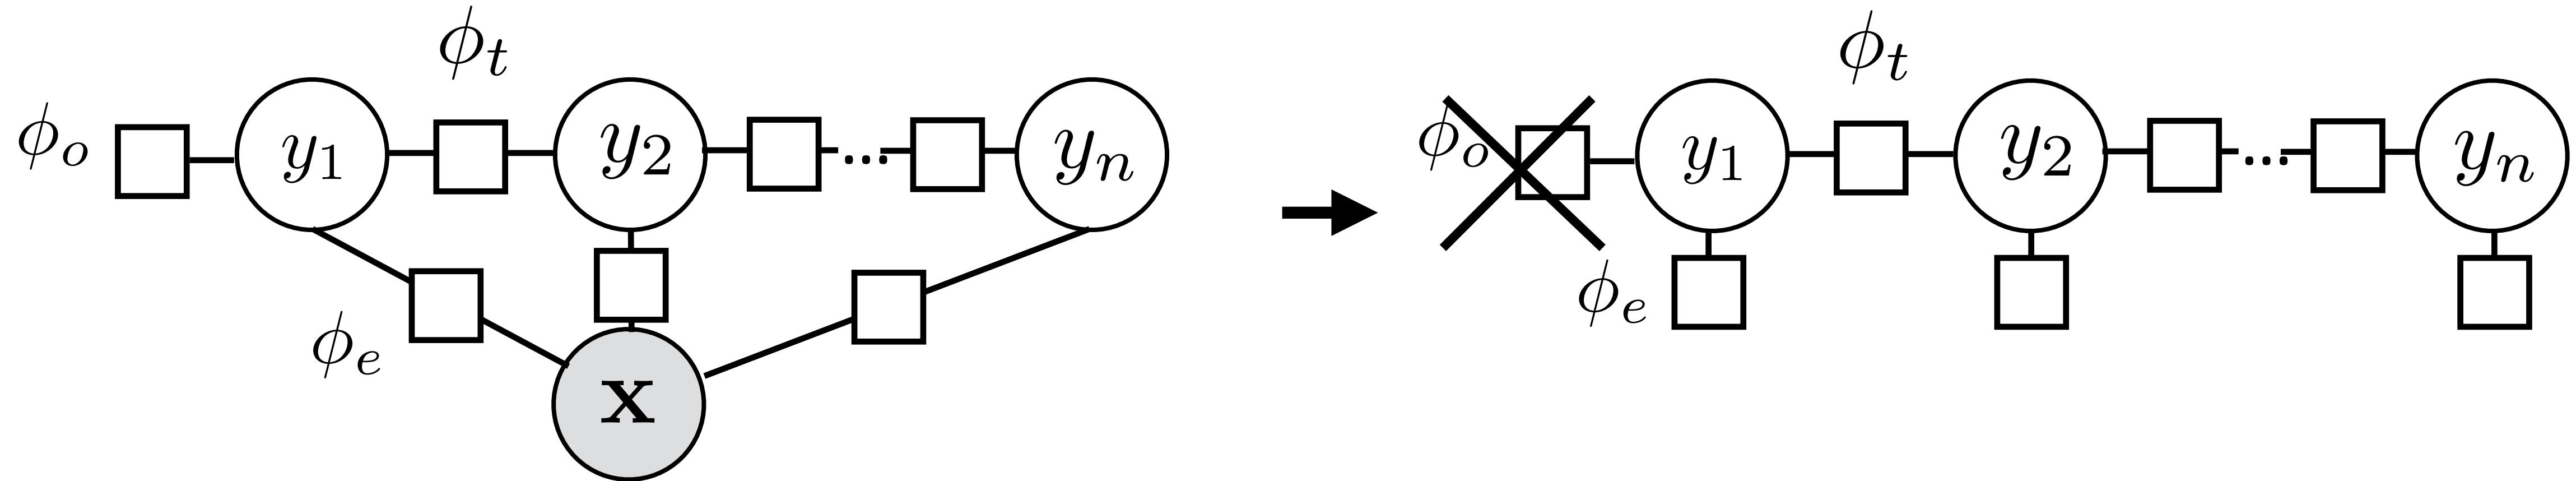

$$P(\mathbf{y}|\mathbf{x}) \propto \exp(\phi_o(y_1)) \prod_{i=2}^n \exp(\phi_t(y_{i-1}, y_i)) \prod_{i=1}^n \exp(\phi_e(x_i, y_i))$$

- ▶ We condition on \mathbf{x} , so every factor can depend on all of \mathbf{x} (including transitions, but we won't do this)
- ▶ \mathbf{y} can't depend arbitrarily on \mathbf{x} in a generative model

$$\prod_{i=1}^n \exp(\phi_e(y_i, i, \mathbf{x}))$$

token index — lets us look at current word

Sequential CRFs

- ▶ Notation: omit \mathbf{x} from the factor graph entirely (implicit)
- ▶ Don't include initial distribution, can bake into other factors

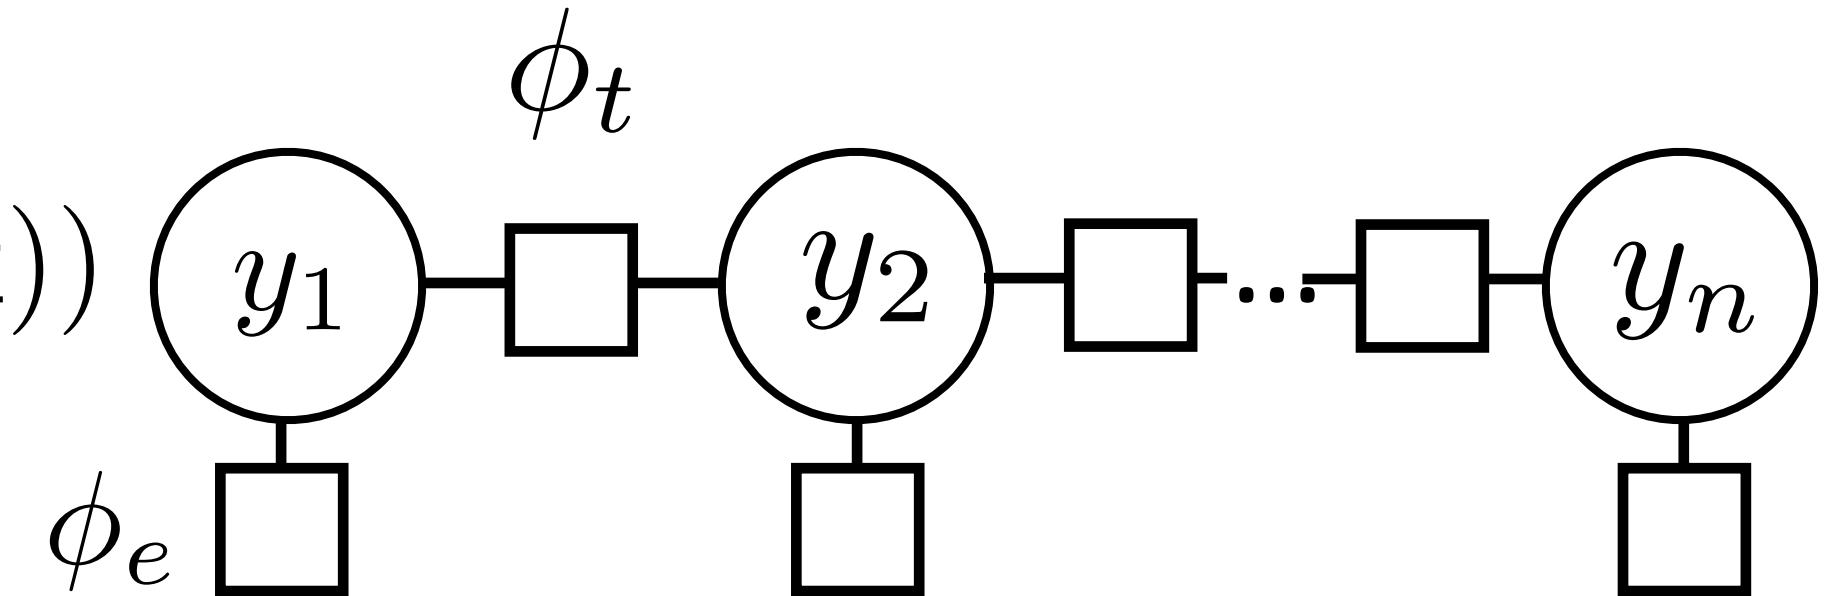

Sequential CRFs:

$$P(\mathbf{y}|\mathbf{x}) = \frac{1}{Z} \prod_{i=2}^n \exp(\phi_t(y_{i-1}, y_i)) \prod_{i=1}^n \exp(\phi_e(y_i, i, \mathbf{x}))$$

Features for NER

Feature Functions

$$P(\mathbf{y}|\mathbf{x}) = \frac{1}{Z} \prod_{i=2}^n \exp(\phi_t(y_{i-1}, y_i)) \prod_{i=1}^n \exp(\phi_e(y_i, i, \mathbf{x}))$$

- ▶ This can be almost anything! Here we use linear functions of sparse features

$$\phi_e(y_i, i, \mathbf{x}) = w^\top f_e(y_i, i, \mathbf{x}) \quad \phi_t(y_{i-1}, y_i) = w^\top f_t(y_{i-1}, y_i)$$

$$P(\mathbf{y}|\mathbf{x}) \propto \exp w^\top \left[\sum_{i=2}^n f_t(y_{i-1}, y_i) + \sum_{i=1}^n f_e(y_i, i, \mathbf{x}) \right]$$

- ▶ Looks like our single weight vector multiclass logistic regression model

Basic Features for NER

$$P(\mathbf{y}|\mathbf{x}) \propto \exp w^\top \left[\sum_{i=2}^n f_t(y_{i-1}, y_i) + \sum_{i=1}^n f_e(y_i, i, \mathbf{x}) \right]$$

O B-LOC

CRFs Outline

- Model:
$$P(\mathbf{y}|\mathbf{x}) = \frac{1}{Z} \prod_{i=2}^n \exp(\phi_t(y_{i-1}, y_i)) \prod_{i=1}^n \exp(\phi_e(y_i, i, \mathbf{x}))$$
$$P(\mathbf{y}|\mathbf{x}) \propto \exp w^\top \left[\sum_{i=2}^n f_t(y_{i-1}, y_i) + \sum_{i=1}^n f_e(y_i, i, \mathbf{x}) \right]$$
- Inference
- Learning

Inference and Learning in CRFs

Computing (arg)maxes

$$P(\mathbf{y}|\mathbf{x}) = \frac{1}{Z} \prod_{i=2}^n \exp(\phi_t(y_{i-1}, y_i)) \prod_{i=1}^n \exp(\phi_e(y_i, i, \mathbf{x}))$$

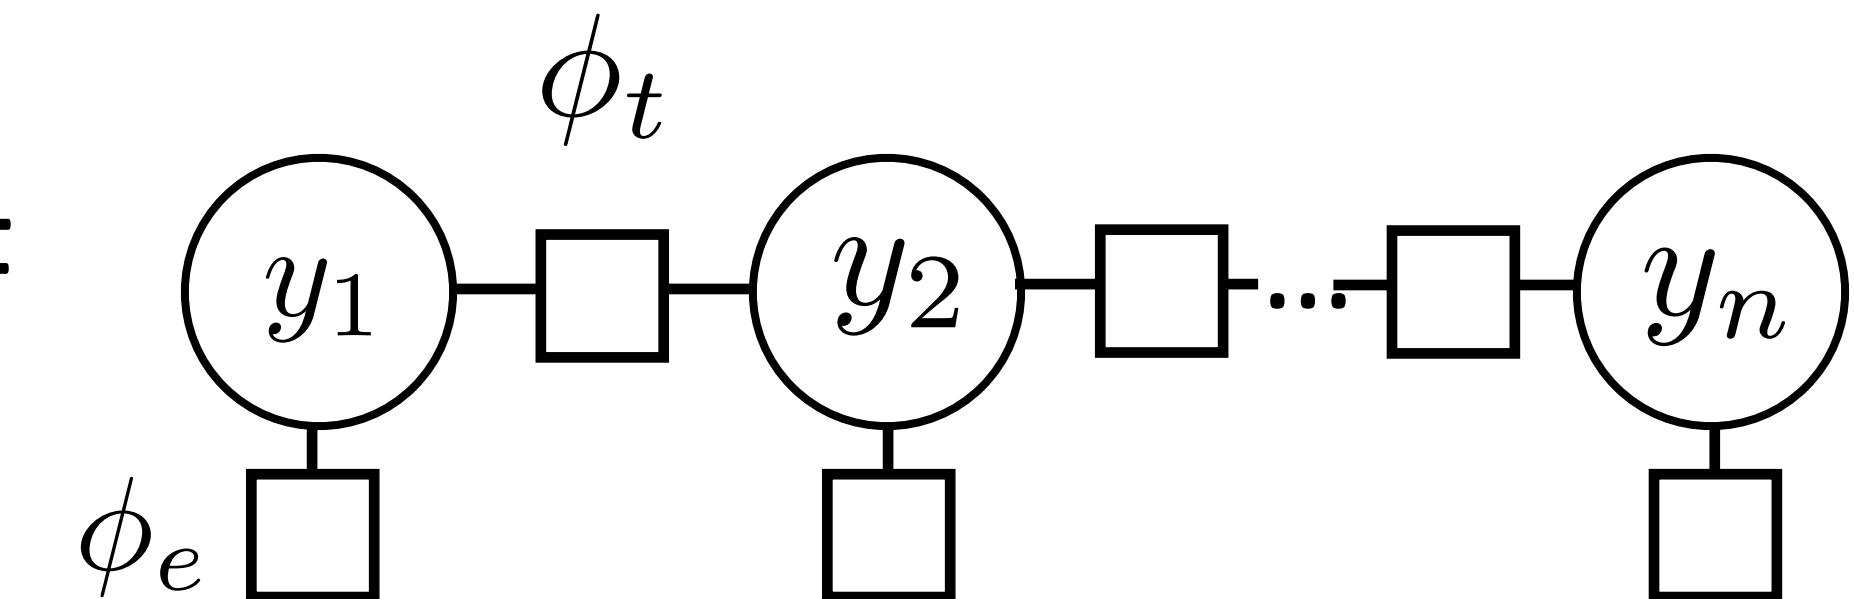

- $\text{argmax}_{\mathbf{y}} P(\mathbf{y}|\mathbf{x})$: can use Viterbi exactly as in HMM case

$$\begin{aligned} & \max_{y_1, \dots, y_n} e^{\phi_t(y_{n-1}, y_n)} e^{\phi_e(y_n, n, \mathbf{x})} \dots e^{\phi_e(y_2, 2, \mathbf{x})} e^{\phi_t(y_1, y_2)} e^{\phi_e(y_1, 1, \mathbf{x})} \\ &= \max_{y_2, \dots, y_n} e^{\phi_t(y_{n-1}, y_n)} e^{\phi_e(y_n, n, \mathbf{x})} \dots e^{\phi_e(y_2, 2, \mathbf{x})} \boxed{\max_{y_1} e^{\phi_t(y_1, y_2)}} \underbrace{e^{\phi_e(y_1, 1, \mathbf{x})}}_{\text{score}_1(y_1)} \end{aligned}$$

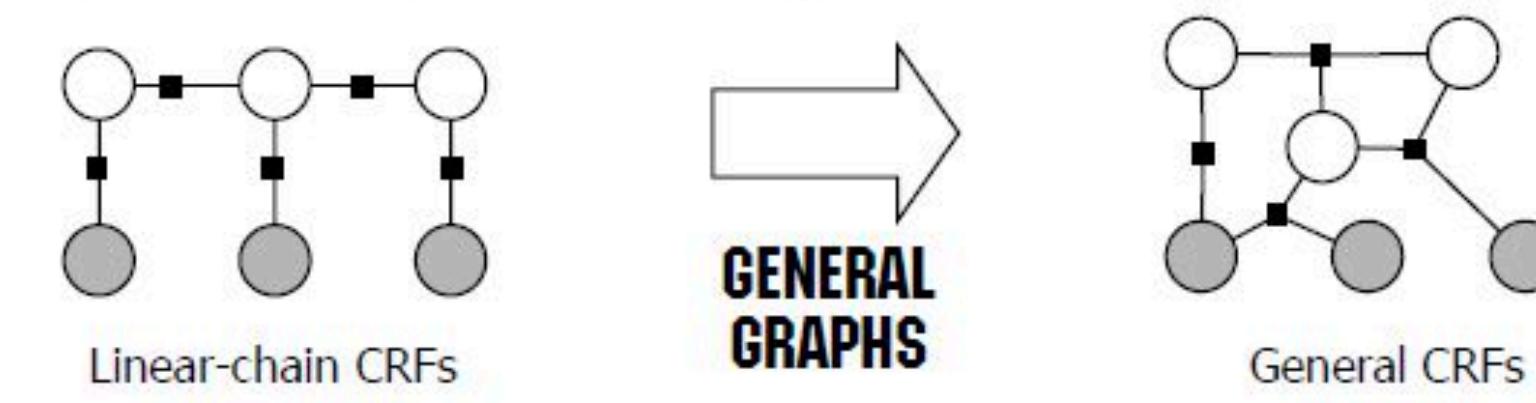

- $\exp(\phi_t(y_{i-1}, y_i))$ and $\exp(\phi_e(y_i, i, \mathbf{x}))$ play the role of the Ps now, same dynamic program

Inference in General CRFs

- ▶ Can do inference in any tree-structured CRF

- ▶ Max-product algorithm: generalization of Viterbi to arbitrary tree-structured graphs (sum-product is generalization of forward-backward)

CRFs Outline

- Model: $P(\mathbf{y}|\mathbf{x}) = \frac{1}{Z} \prod_{i=2}^n \exp(\phi_t(y_{i-1}, y_i)) \prod_{i=1}^n \exp(\phi_e(y_i, i, \mathbf{x}))$
$$P(\mathbf{y}|\mathbf{x}) \propto \exp w^\top \left[\sum_{i=2}^n f_t(y_{i-1}, y_i) + \sum_{i=1}^n f_e(y_i, i, \mathbf{x}) \right]$$
- Inference: $\text{argmax } P(\mathbf{y}|\mathbf{x})$ from Viterbi
- Learning

Training CRFs

$$P(\mathbf{y}|\mathbf{x}) \propto \exp w^\top \left[\sum_{i=2}^n f_t(y_{i-1}, y_i) + \sum_{i=1}^n f_e(y_i, i, \mathbf{x}) \right]$$

- ▶ Logistic regression: $P(y|x) \propto \exp w^\top f(x, y)$
- ▶ Maximize $\mathcal{L}(\mathbf{y}^*, \mathbf{x}) = \log P(\mathbf{y}^*|\mathbf{x})$
- ▶ Gradient is completely analogous to logistic regression:

$$\frac{\partial}{\partial w} \mathcal{L}(\mathbf{y}^*, \mathbf{x}) = \sum_{i=2}^n f_t(y_{i-1}^*, y_i^*) + \sum_{i=1}^n f_e(y_i^*, i, \mathbf{x})$$

intractable! $\xrightarrow{-\mathbb{E}_{\mathbf{y}} \left[\sum_{i=2}^n f_t(y_{i-1}, y_i) + \sum_{i=1}^n f_e(y_i, i, \mathbf{x}) \right]}$

Training CRFs

$$\begin{aligned}\frac{\partial}{\partial w} \mathcal{L}(\mathbf{y}^*, \mathbf{x}) &= \sum_{i=2}^n f_t(y_{i-1}^*, y_i^*) + \sum_{i=1}^n f_e(y_i^*, i, \mathbf{x}) \\ &\quad - \mathbb{E}_{\mathbf{y}} \left[\sum_{i=2}^n f_t(y_{i-1}, y_i) + \sum_{i=1}^n f_e(y_i, i, \mathbf{x}) \right]\end{aligned}$$

► Let's focus on emission feature expectation

$$\begin{aligned}\mathbb{E}_{\mathbf{y}} \left[\sum_{i=1}^n f_e(y_i, i, \mathbf{x}) \right] &= \sum_{\mathbf{y} \in \mathcal{Y}} P(\mathbf{y}|\mathbf{x}) \left[\sum_{i=1}^n f_e(y_i, i, \mathbf{x}) \right] = \sum_{i=1}^n \sum_{\mathbf{y} \in \mathcal{Y}} P(\mathbf{y}|\mathbf{x}) f_e(y_i, i, \mathbf{x}) \\ &= \sum_{i=1}^n \sum_s P(y_i = s | \mathbf{x}) f_e(s, i, \mathbf{x})\end{aligned}$$

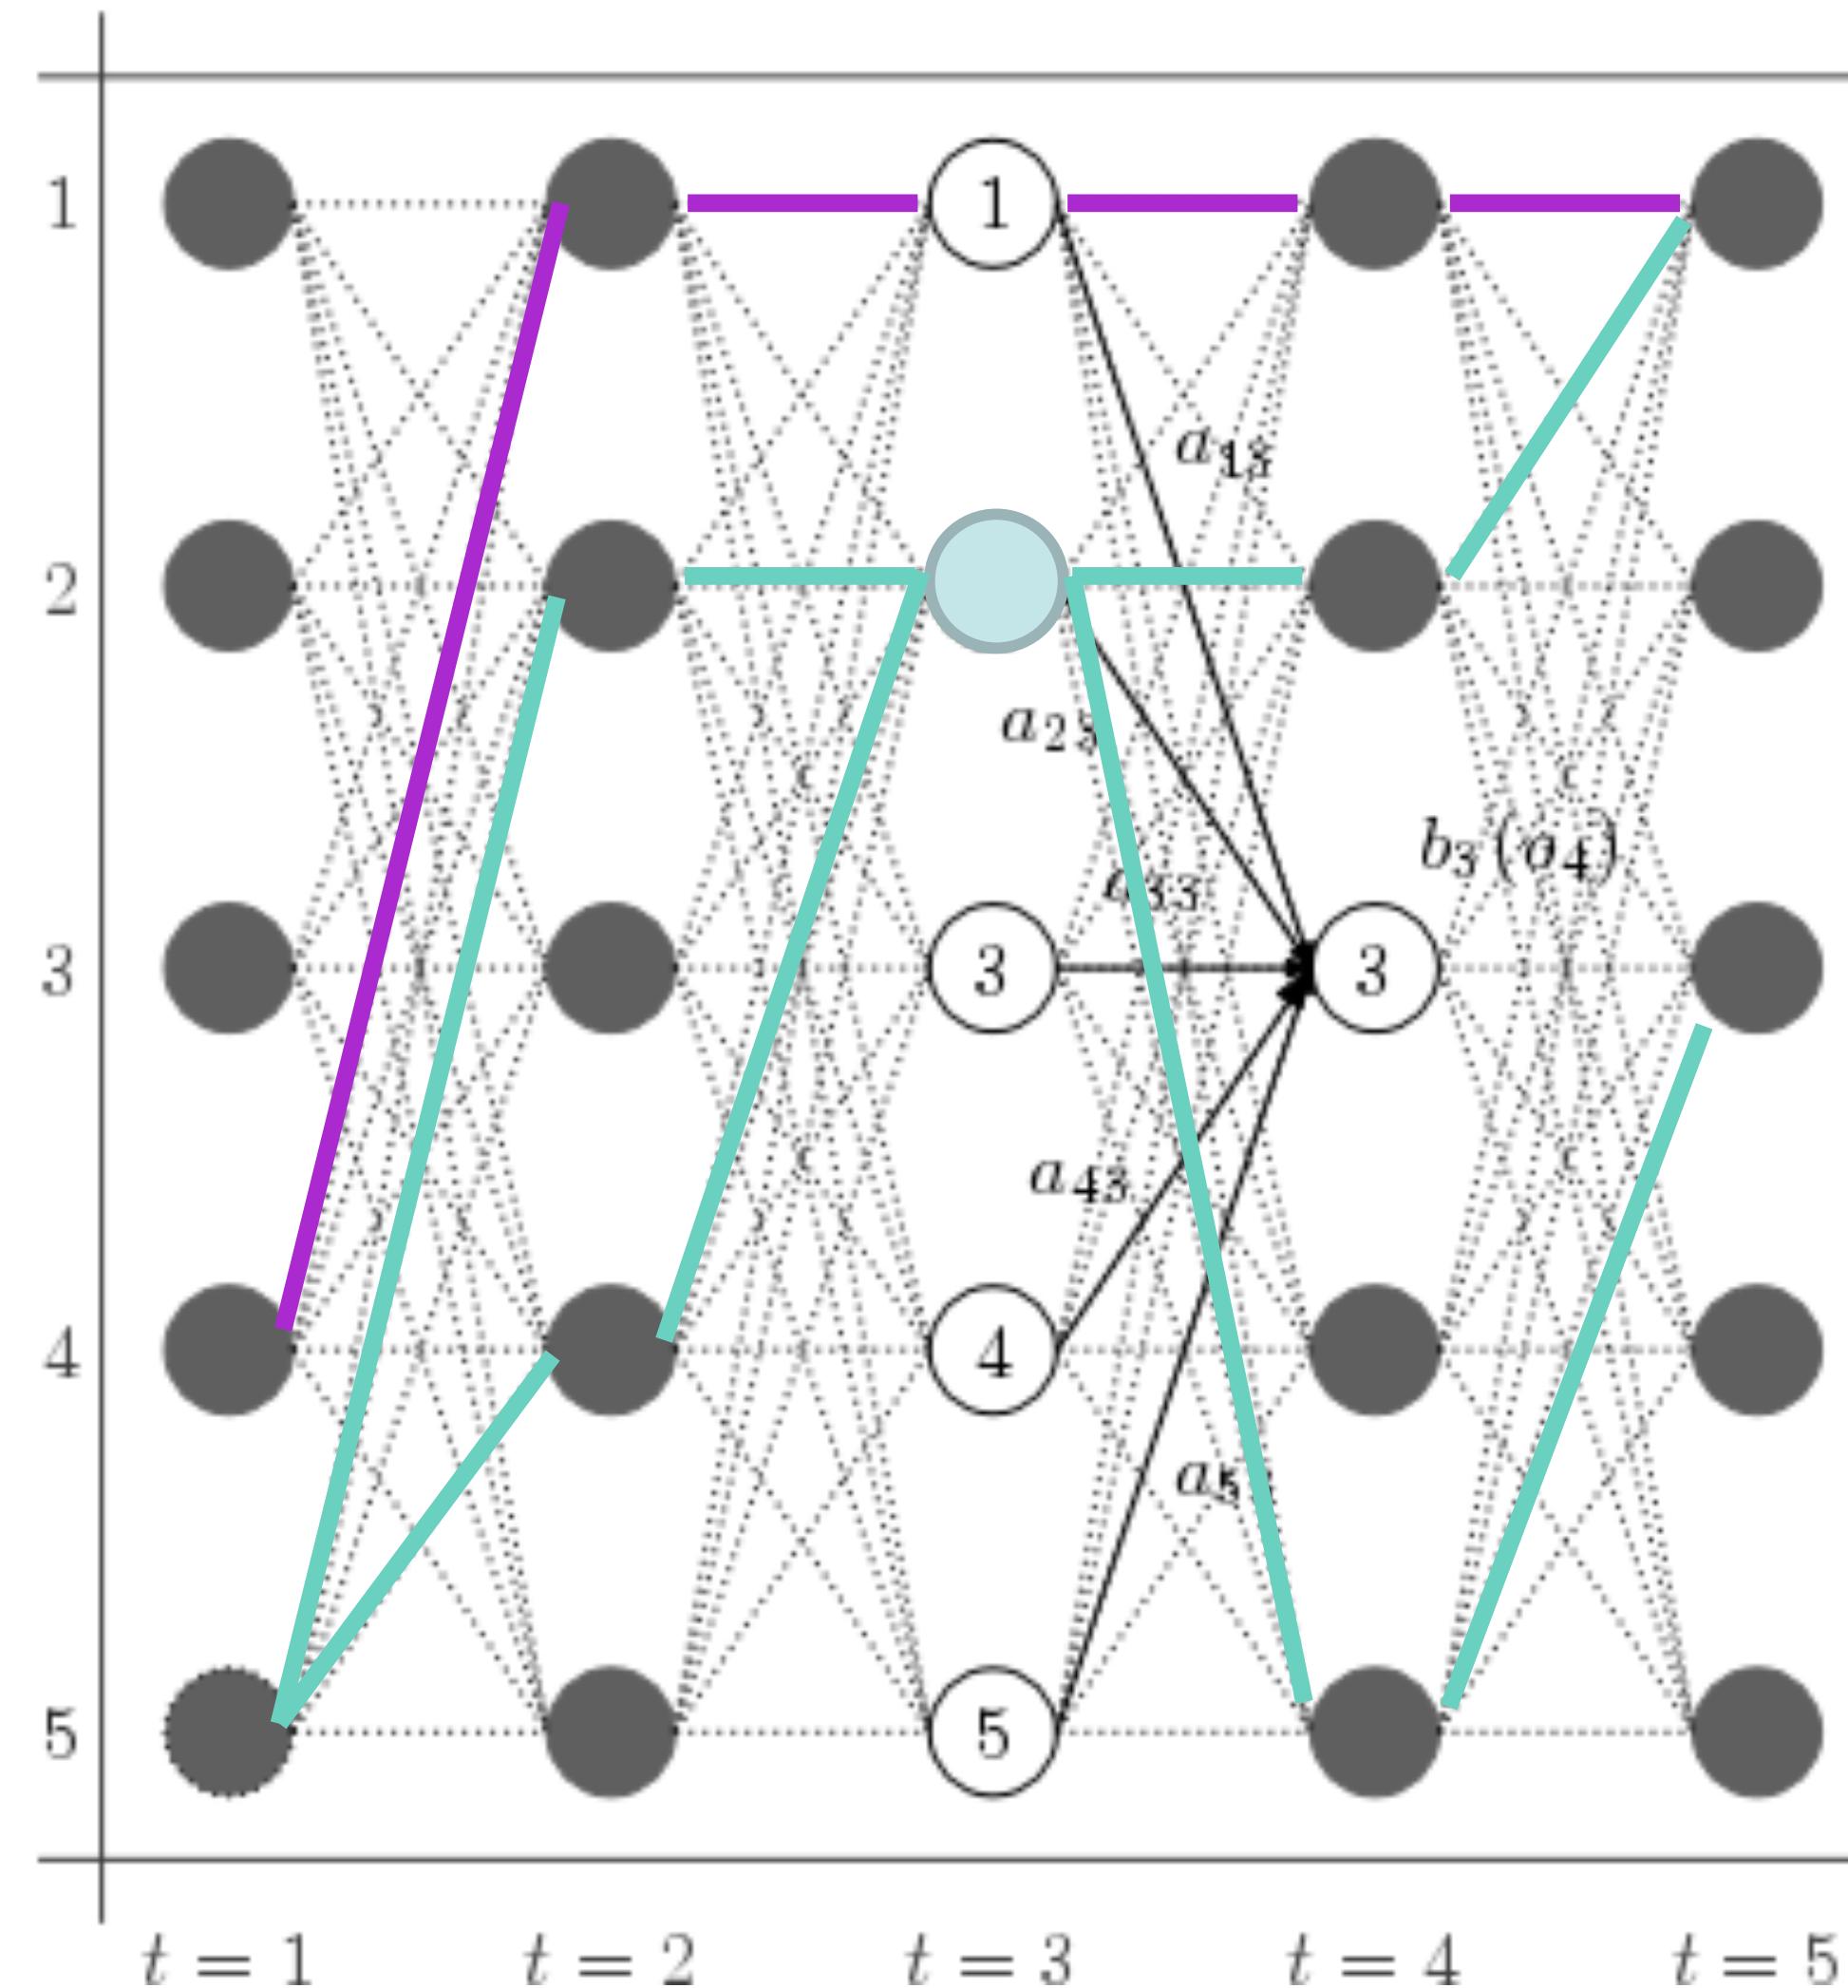

Forward-Backward Algorithm

- ▶ How do we compute these marginals $P(y_i = s|\mathbf{x})$?

$$P(y_i = s|\mathbf{x}) = \sum_{y_1, \dots, y_{i-1}, y_{i+1}, \dots, y_n} P(\mathbf{y}|\mathbf{x})$$

- ▶ What did Viterbi compute? $P(\mathbf{y}_{\max}|\mathbf{x}) = \max_{y_1, \dots, y_n} P(\mathbf{y}|\mathbf{x})$
- ▶ Can compute marginals with dynamic programming as well using the forward-backward algorithm

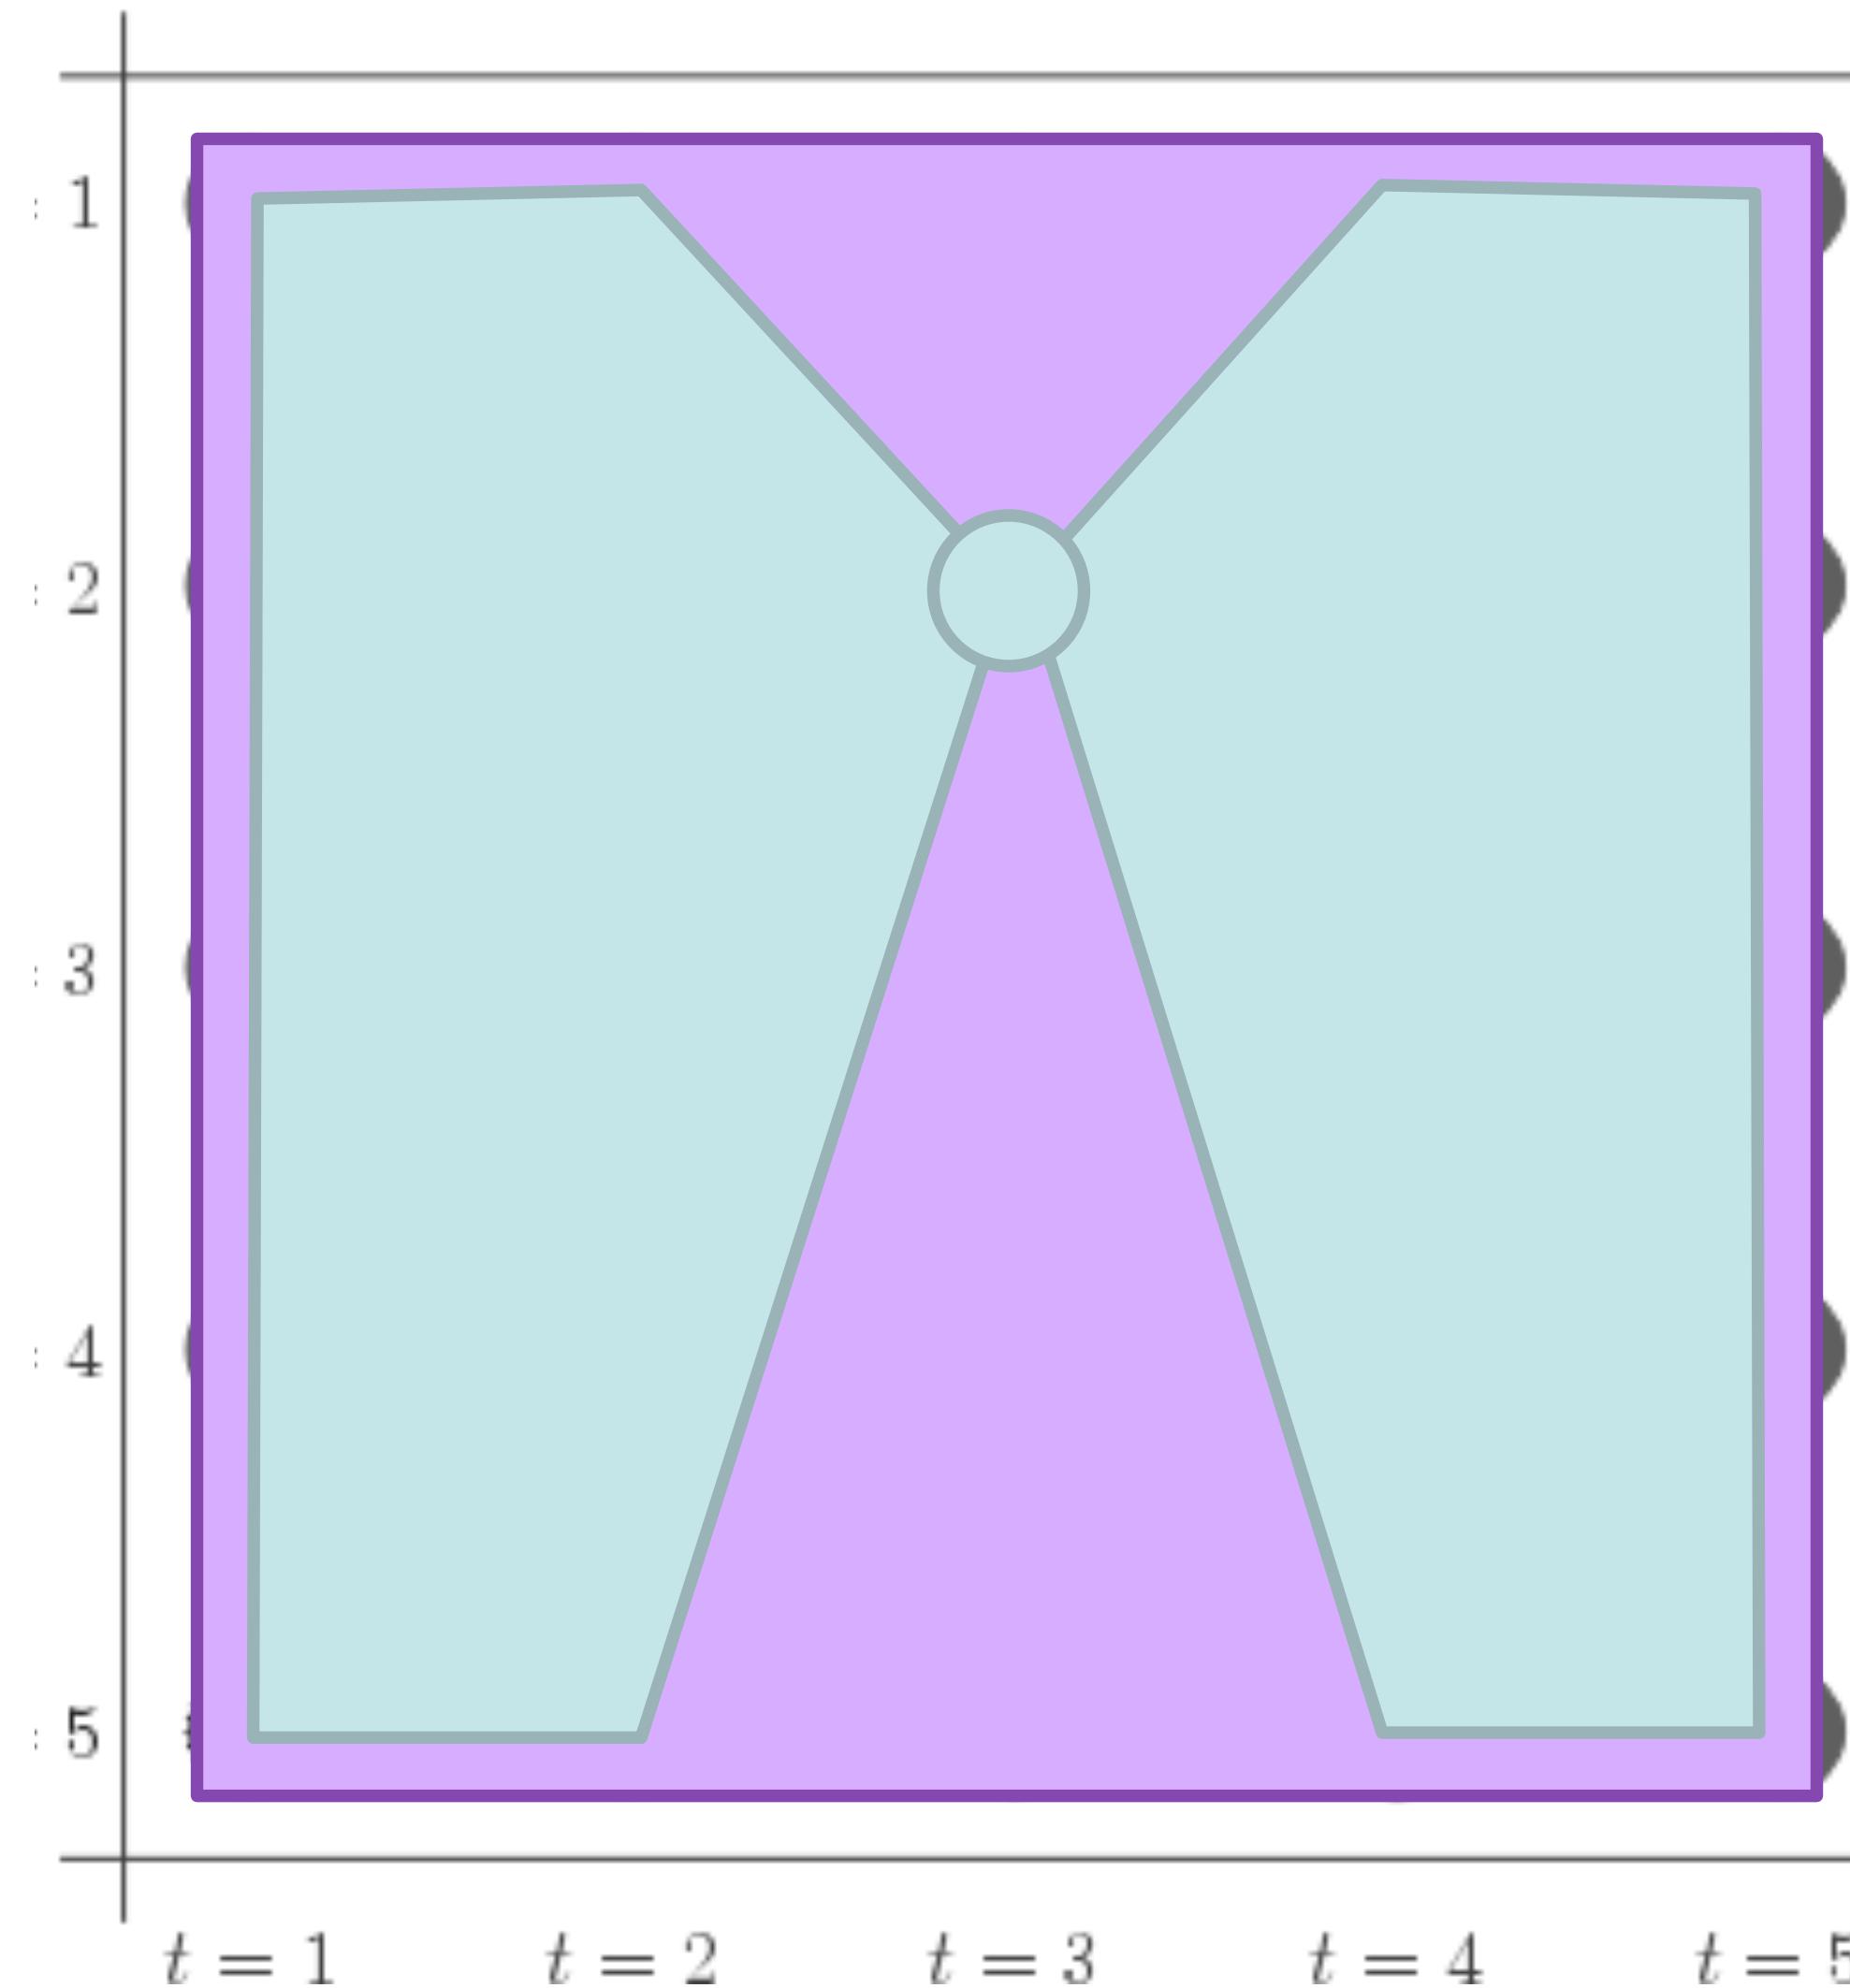

Forward-Backward Algorithm

$$P(y_3 = 2 | \mathbf{x}) =$$

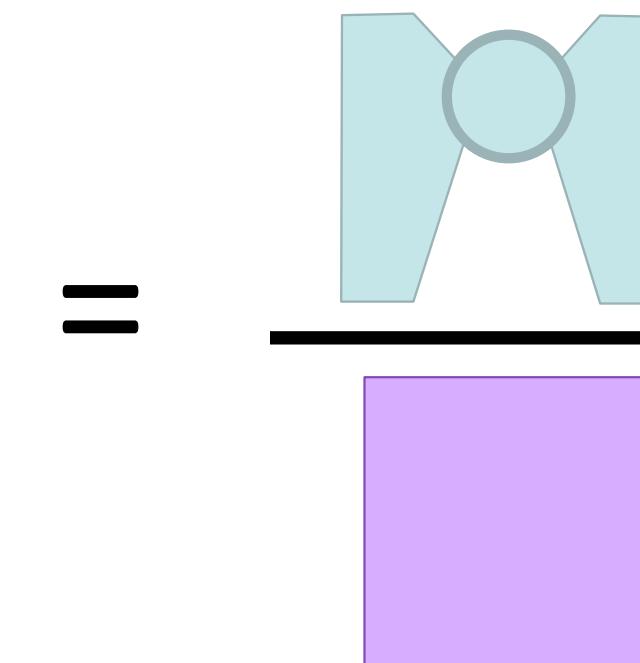

$$\frac{\text{sum of all paths through state 2 at time 3}}{\text{sum of all paths}}$$

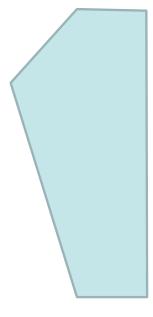

Forward-Backward Algorithm

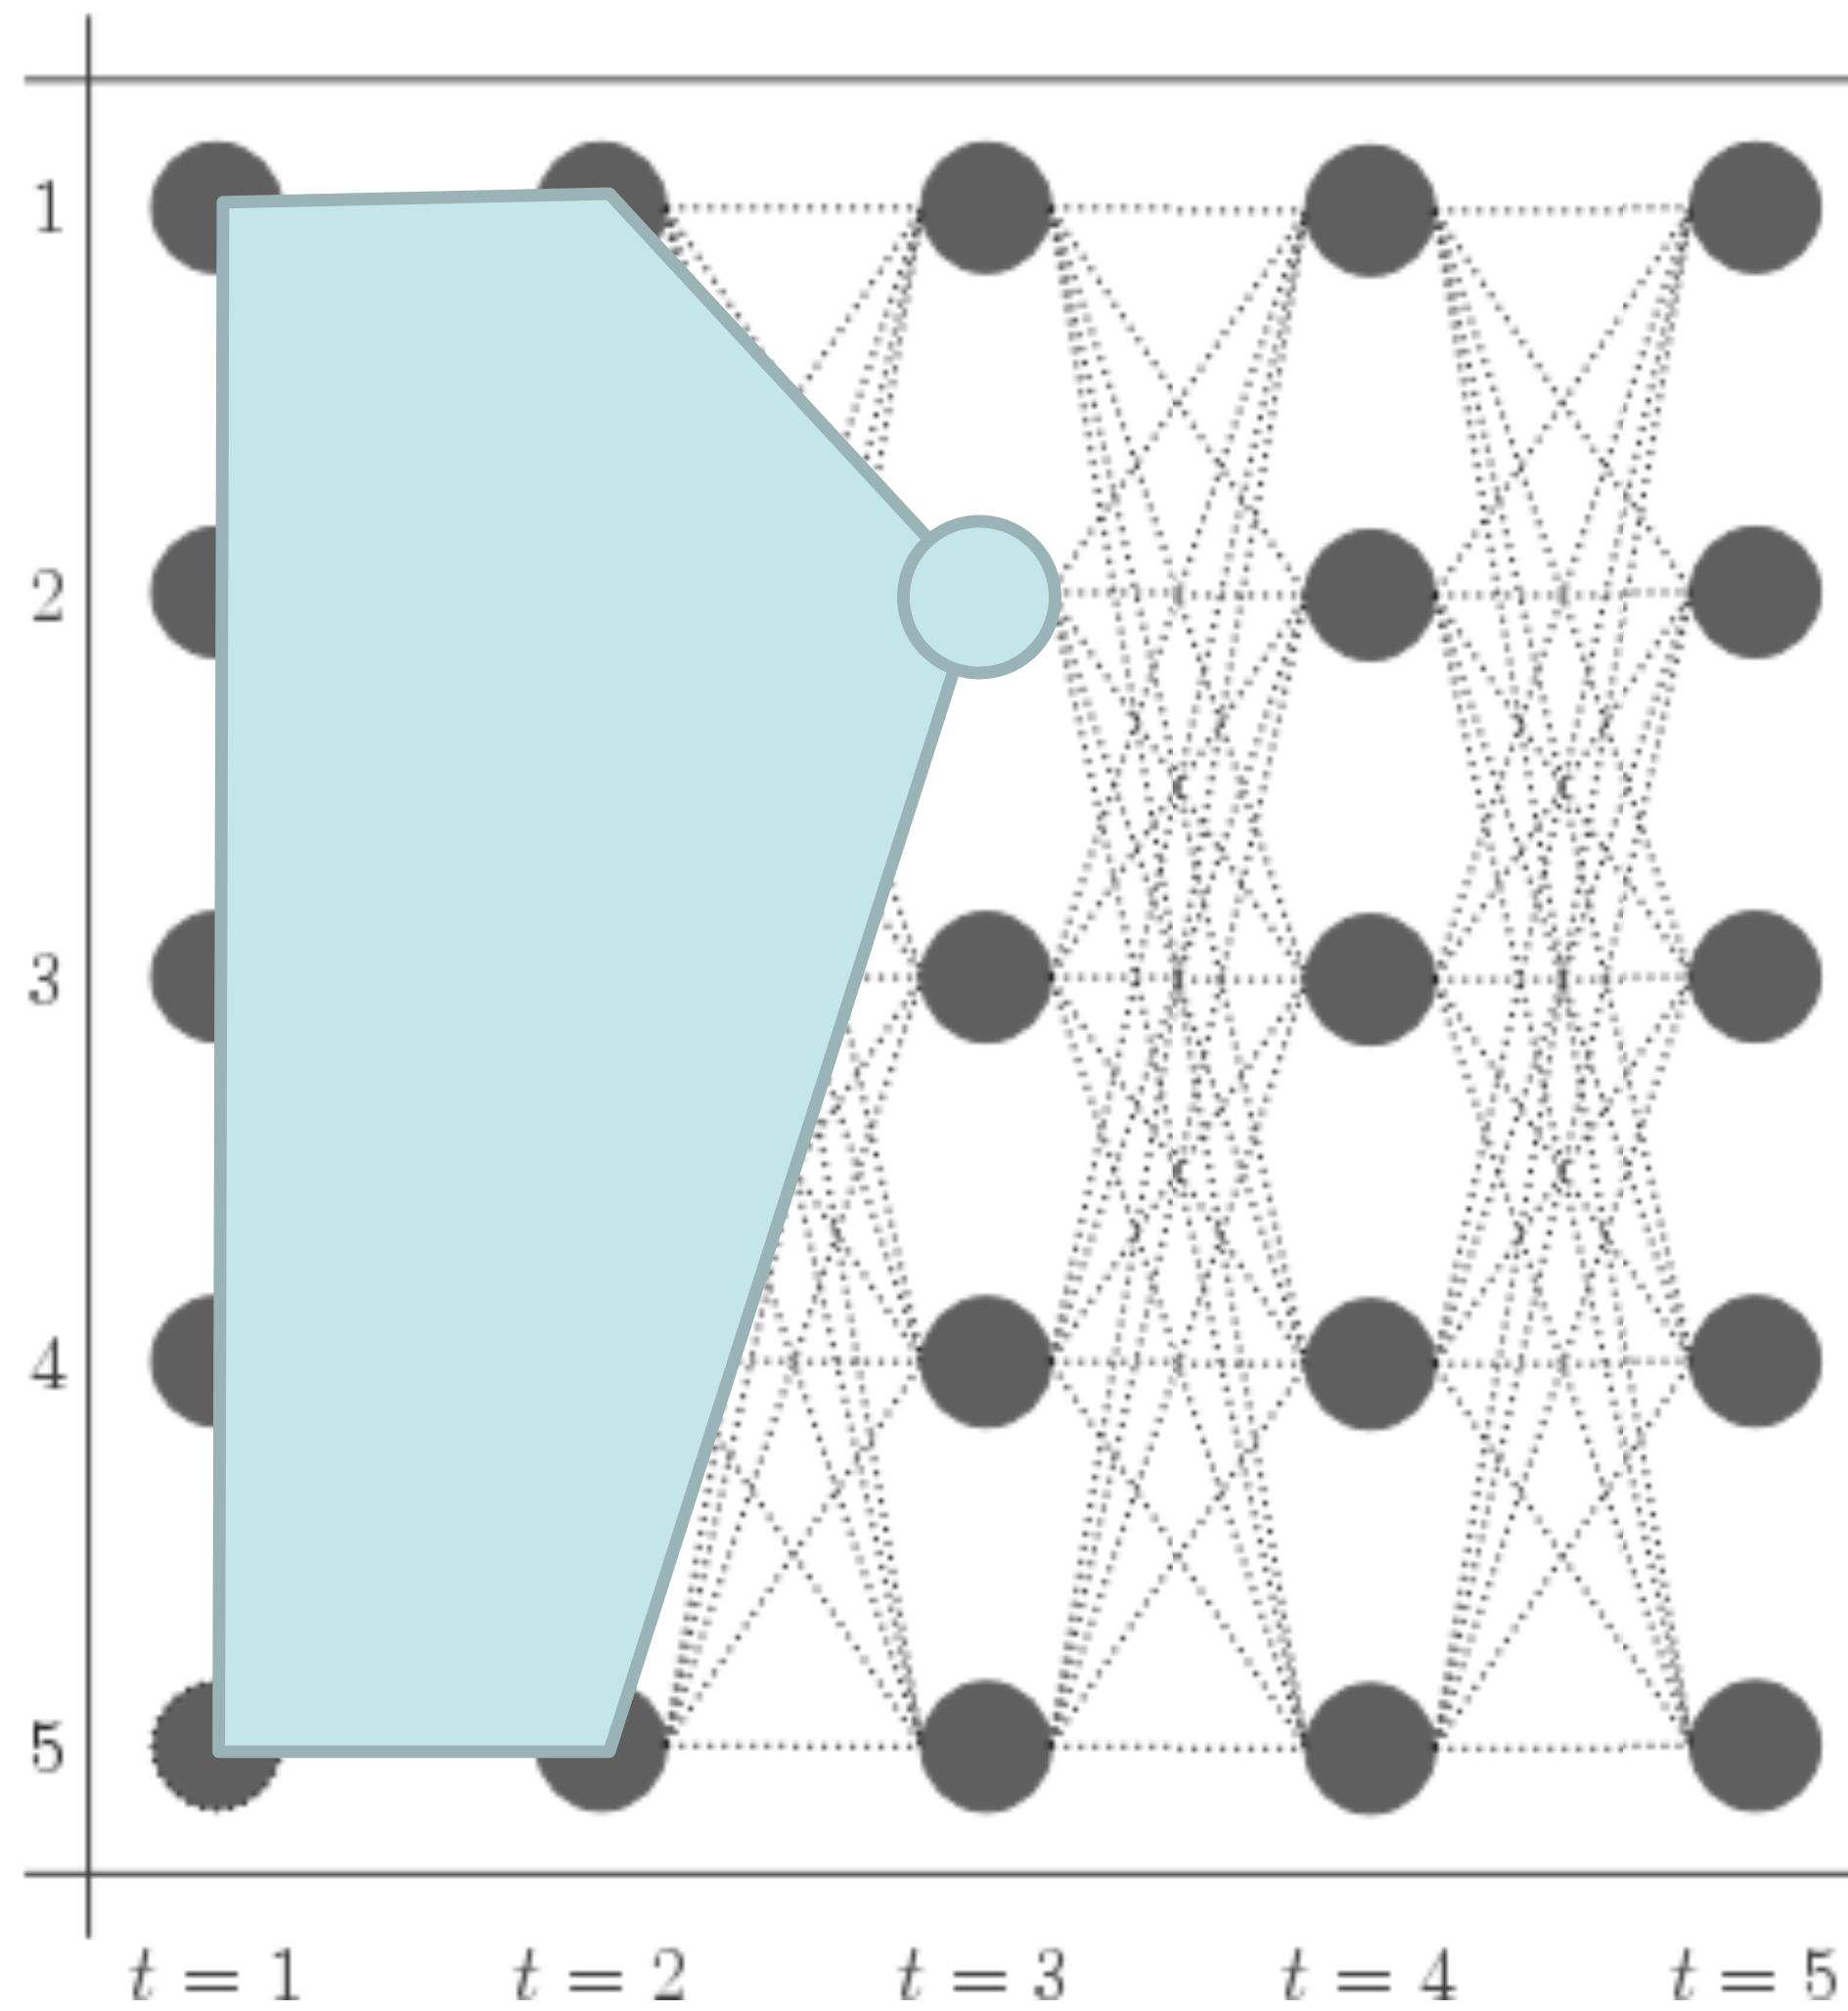

$$P(y_3 = 2 | \mathbf{x}) =$$

$$\frac{\text{sum of all paths through state 2 at time 3}}{\text{sum of all paths}}$$

- ▶ Easiest and most flexible to do one pass to compute  and one to compute 

Forward-Backward Algorithm

► Initial:

$$\alpha_1(s) = \exp(\phi_e(s, 1, \mathbf{x}))$$

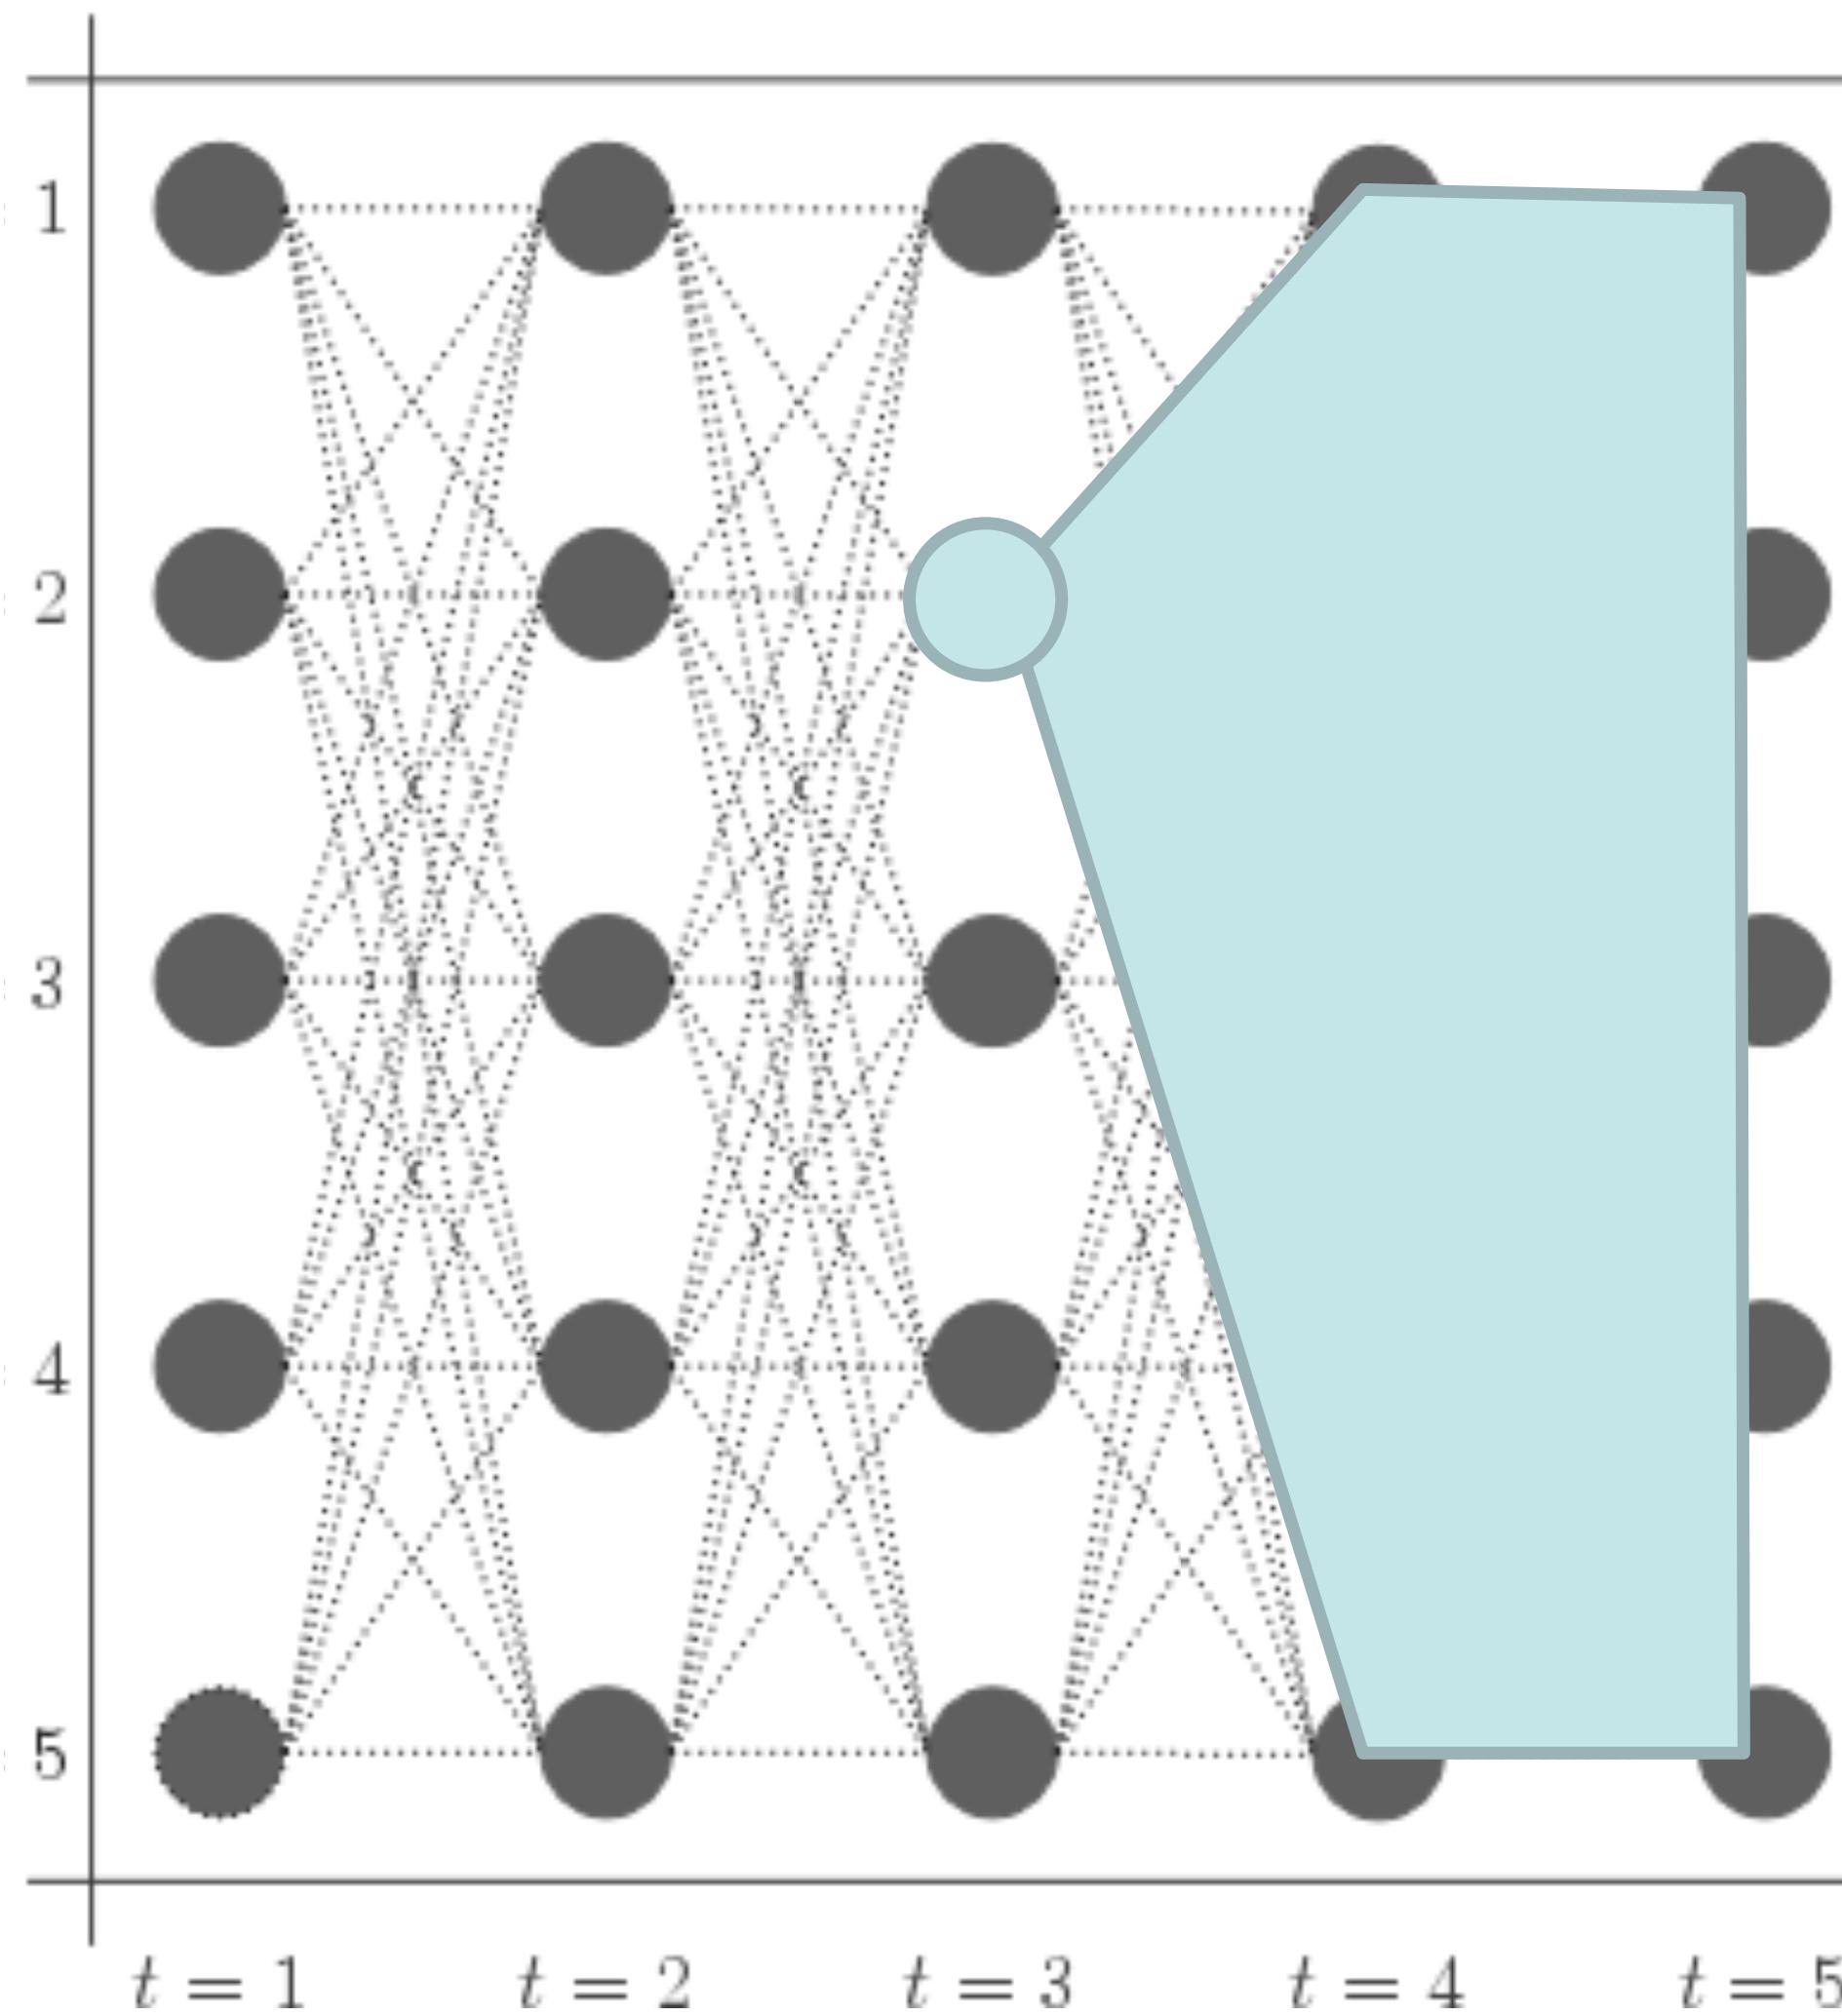

► Recurrence:

$$\alpha_t(s_t) = \sum_{s_{t-1}} \alpha_{t-1}(s_{t-1}) \exp(\phi_e(s_t, t, \mathbf{x})) \\ \exp(\phi_t(s_{t-1}, s_t))$$

► Same as Viterbi but summing instead of maxing!

► These quantities get very small!
Store everything as log probabilities

Forward-Backward Algorithm

► Initial:

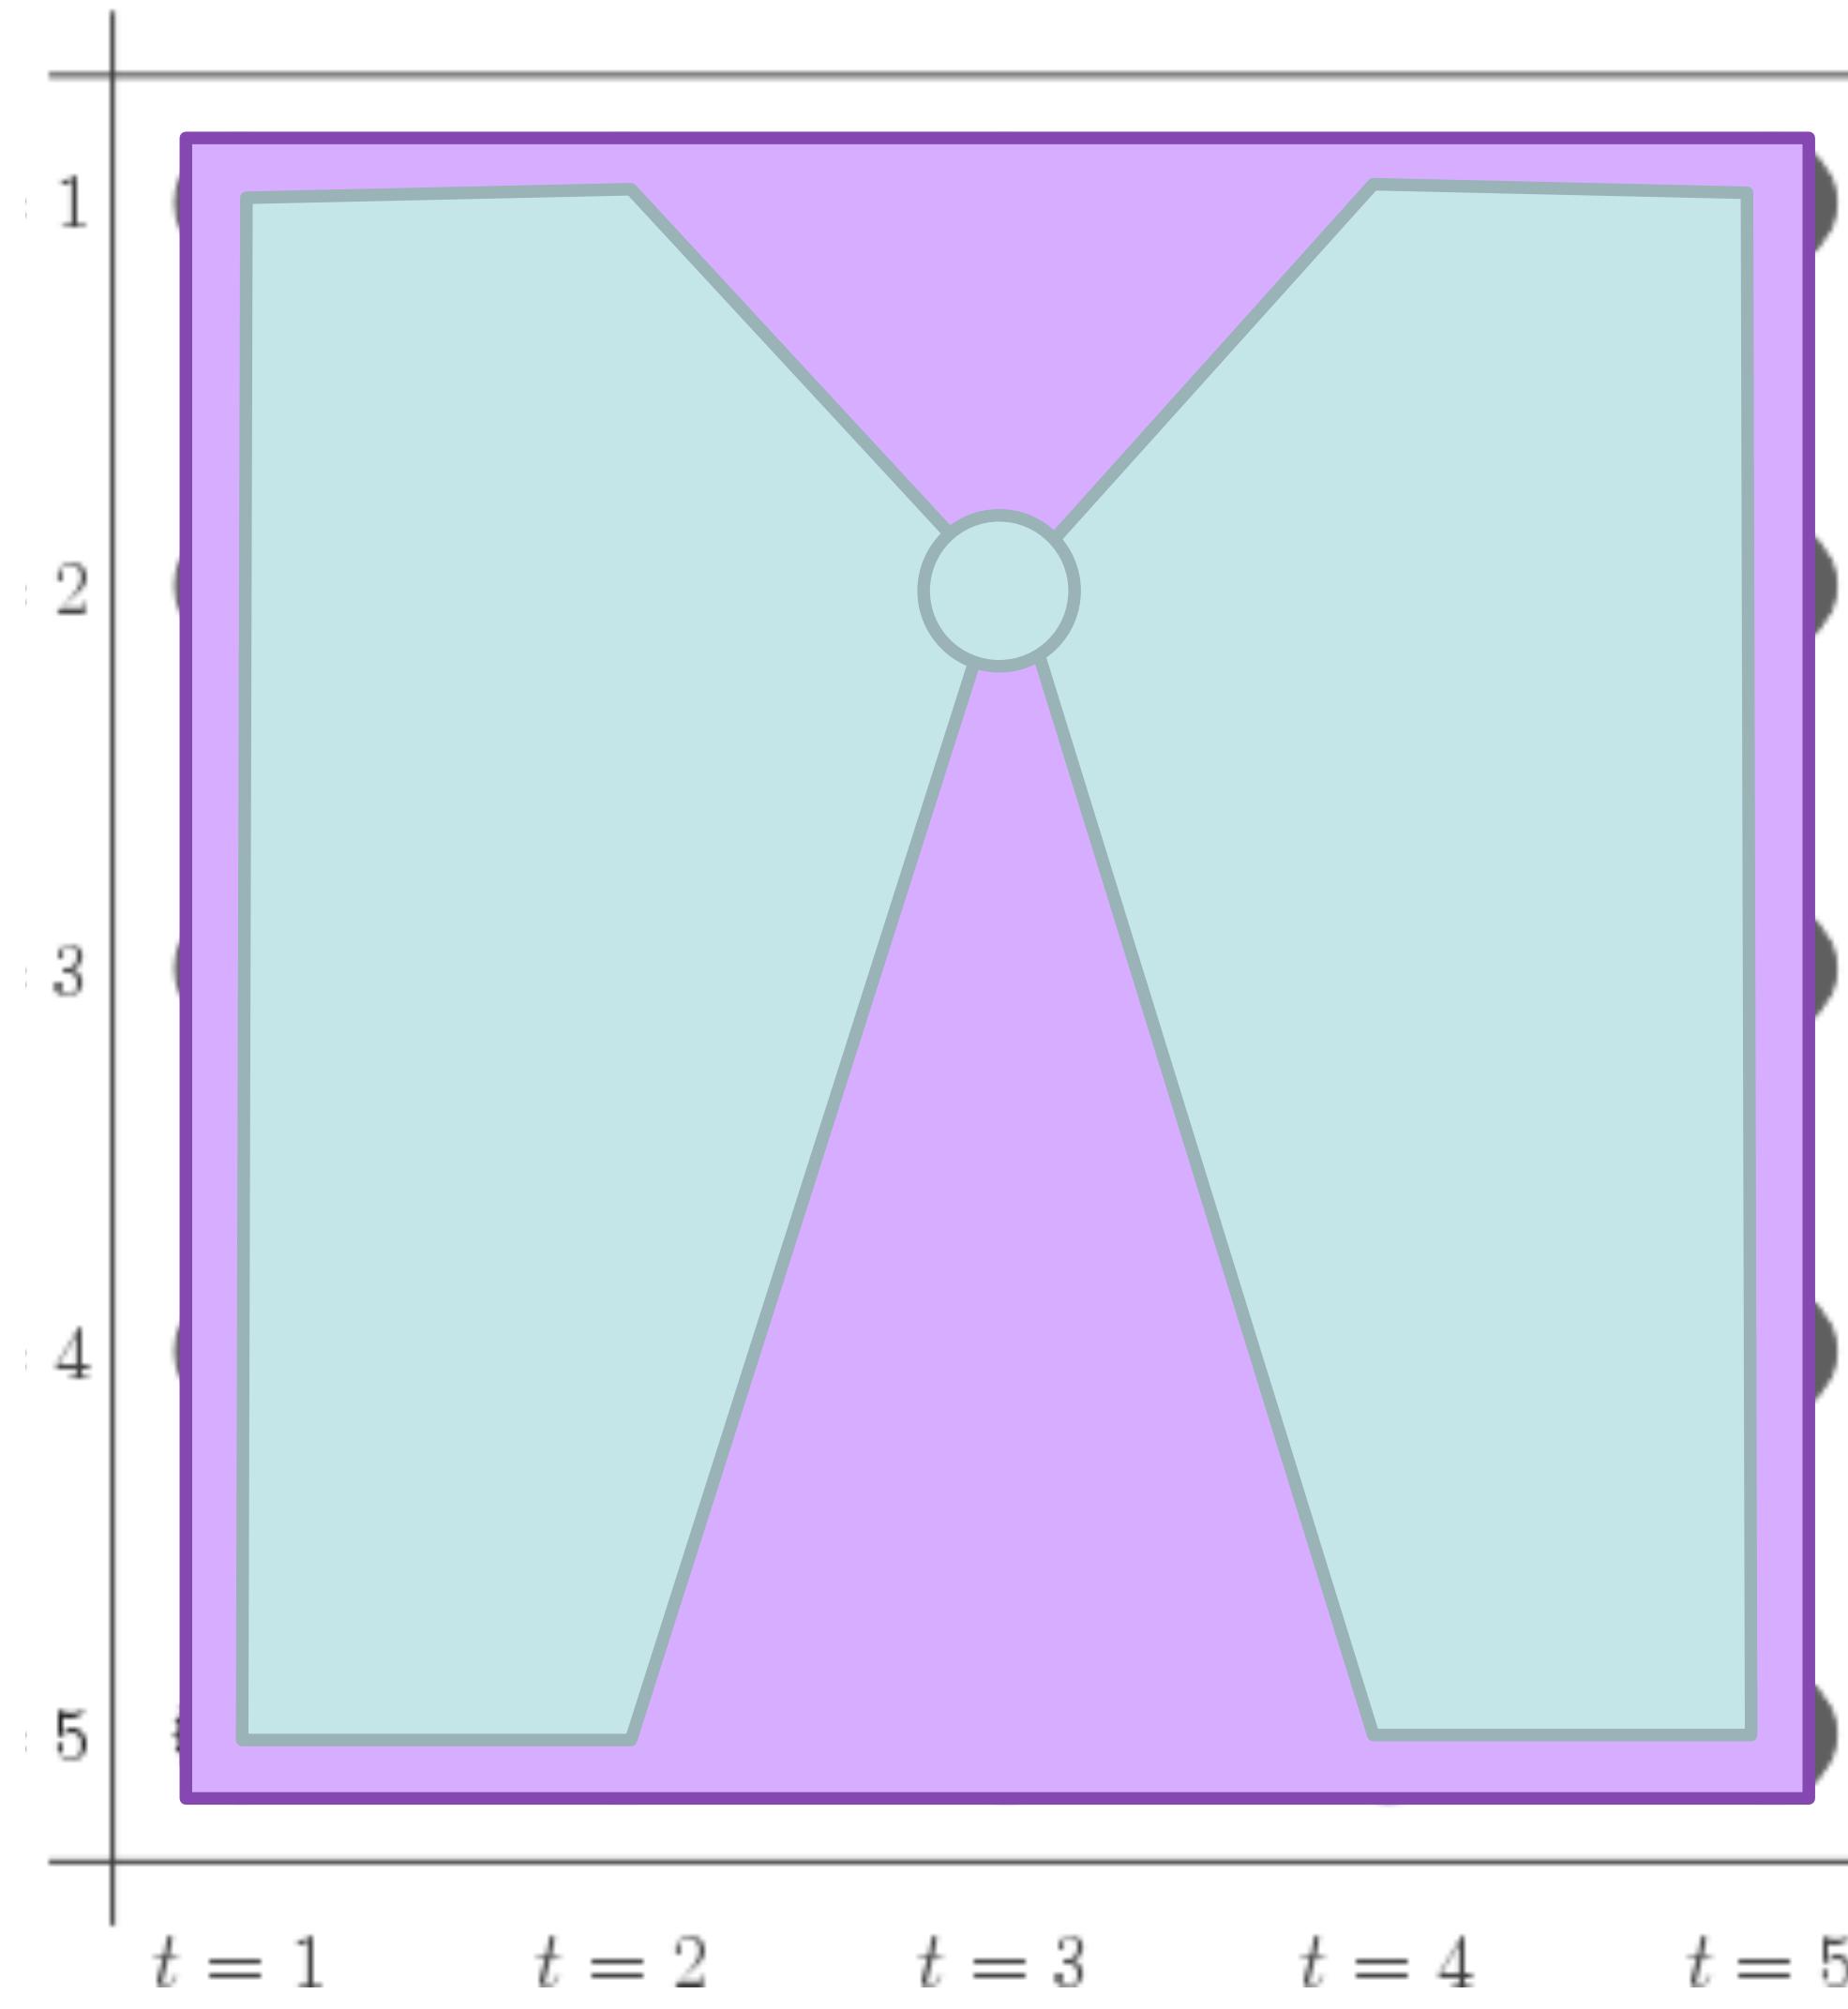

$$\beta_n(s) = 1$$

► Recurrence:

$$\beta_t(s_t) = \sum_{s_{t+1}} \beta_{t+1}(s_{t+1}) \exp(\phi_e(s_{t+1}, t + 1, \mathbf{x})) \\ \exp(\phi_t(s_t, s_{t+1}))$$

► Big differences: count emission for the *next timestep* (not current one)

Forward-Backward Algorithm

$$\alpha_1(s) = \exp(\phi_e(s, 1, \mathbf{x}))$$

$$\alpha_t(s_t) = \sum_{s_{t-1}} \alpha_{t-1}(s_{t-1}) \exp(\phi_e(s_t, t, \mathbf{x})) \\ \exp(\phi_t(s_{t-1}, s_t))$$

$$\beta_n(s) = 1$$

$$\beta_t(s_t) = \sum_{s_{t+1}} \beta_{t+1}(s_{t+1}) \exp(\phi_e(s_{t+1}, t + 1, \mathbf{x})) \\ \exp(\phi_t(s_t, s_{t+1}))$$

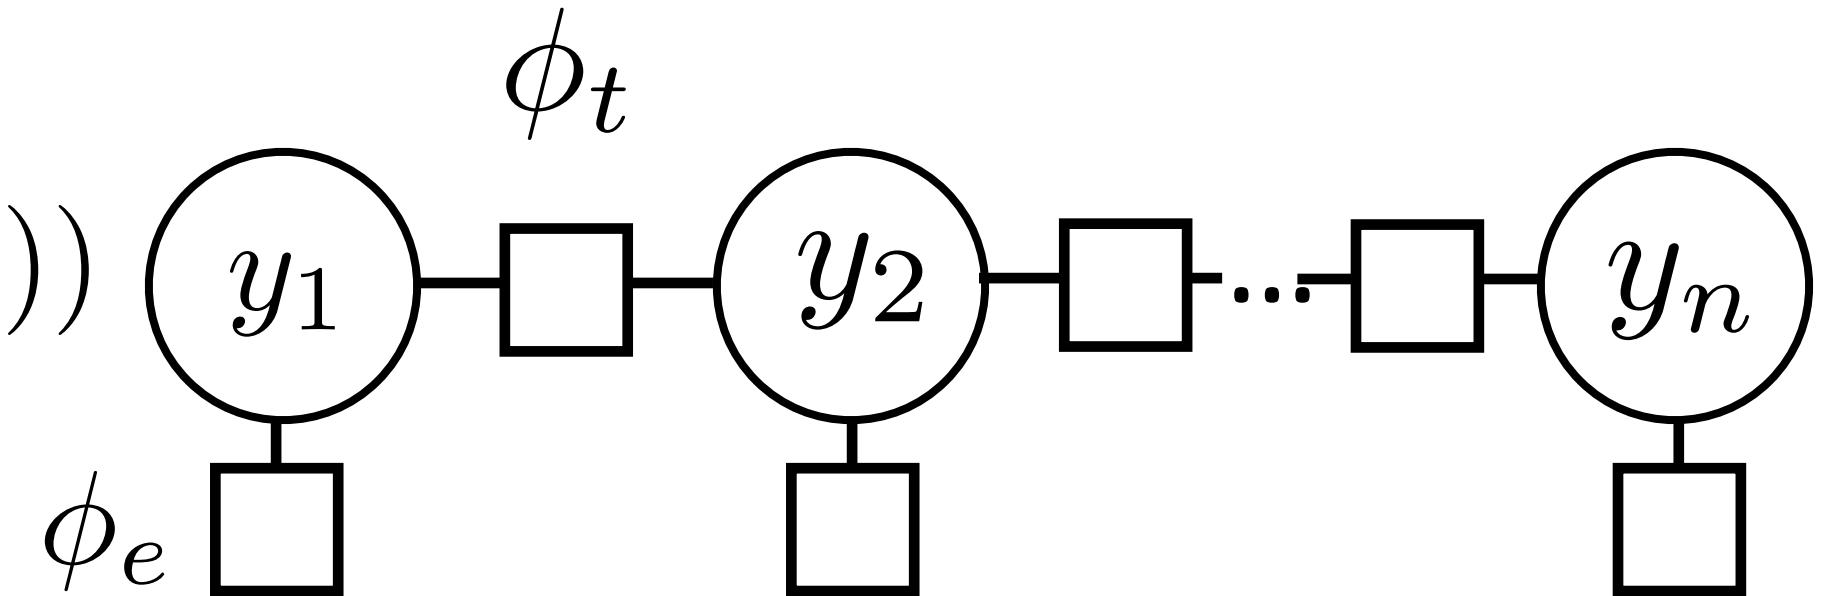

$$P(s_3 = 2 | \mathbf{x}) = \frac{\alpha_3(2)\beta_3(2)}{\sum_i \alpha_3(i)\beta_3(i)} = \frac{\text{[Diagram showing a light blue trapezoid with a central circle and a light purple trapezoid below it]}}{\text{[Diagram showing a light purple trapezoid]}}$$

► What is the denominator here?

Z

Computing Marginals

$$P(\mathbf{y}|\mathbf{x}) = \frac{1}{Z} \prod_{i=2}^n \exp(\phi_t(y_{i-1}, y_i)) \prod_{i=1}^n \exp(\phi_e(y_i, i, \mathbf{x}))$$

- ▶ Normalizing constant $Z = \sum_{\mathbf{y}} \prod_{i=2}^n \exp(\phi_t(y_{i-1}, y_i)) \prod_{i=1}^n \exp(\phi_e(y_i, i, \mathbf{x}))$
- ▶ Analogous to $P(\mathbf{x})$ for HMMs
- ▶ For both HMMs and CRFs:

$$P(y_i = s | \mathbf{x}) = \frac{\text{forward}_i(s) \text{backward}_i(s)}{\sum_{s'} \text{forward}_i(s') \text{backward}_i(s')}$$

↗ P(\mathbf{x}) for HMMs
Z for CRFs,

Training CRFs

- ▶ For emission features:

$$\frac{\partial}{\partial w} \mathcal{L}(\mathbf{y}^*, \mathbf{x}) = \sum_{i=1}^n f_e(y_i^*, i, \mathbf{x}) - \sum_{i=1}^n \sum_s P(y_i = s | \mathbf{x}) f_e(s, i, \mathbf{x})$$

gold features – expected features under model

- ▶ Transition features: need to compute $P(y_i = s_1, y_{i+1} = s_2 | \mathbf{x})$ using forward-backward as well
- ▶ ... but, you can build a pretty good system without learned transition features (e.g., use heuristic weights, or just enforce constraints like B-PER -> I-ORG is illegal)

CRFs Outline

- Model:
$$P(\mathbf{y}|\mathbf{x}) = \frac{1}{Z} \prod_{i=2}^n \exp(\phi_t(y_{i-1}, y_i)) \prod_{i=1}^n \exp(\phi_e(y_i, i, \mathbf{x}))$$
$$P(\mathbf{y}|\mathbf{x}) \propto \exp w^\top \left[\sum_{i=2}^n f_t(y_{i-1}, y_i) + \sum_{i=1}^n f_e(y_i, i, \mathbf{x}) \right]$$
- Inference: argmax $P(\mathbf{y}|\mathbf{x})$ from Viterbi
- Learning: run forward-backward to compute posterior probabilities; then

$$\frac{\partial}{\partial w} \mathcal{L}(\mathbf{y}^*, \mathbf{x}) = \sum_{i=1}^n f_e(y_i^*, i, \mathbf{x}) - \sum_{i=1}^n \sum_s P(y_i = s | \mathbf{x}) f_e(s, i, \mathbf{x})$$

Pseudocode

for each epoch

 for each example

- extract features on each emission and transition (look up in cache)
- compute potentials ϕ based on features + weights
- compute marginal probabilities with forward-backward
- accumulate gradient over all emissions and transitions

Implementation Tips for CRFs

- ▶ Caching is your friend! Cache feature vectors especially
- ▶ Try to reduce redundant computation, e.g. if you compute both the gradient and the objective value, don't rerun the dynamic program
- ▶ Exploit sparsity in feature vectors where possible, especially in feature vectors and gradients
- ▶ Do all dynamic program computation in log space to avoid underflow
- ▶ If things are too slow, run a profiler and see where time is being spent. Forward-backward should take most of the time

Debugging Tips for CRFs

- ▶ Hard to know whether inference, learning, or the model is broken!
- ▶ Compute the objective — is optimization working?
 - ▶ **Inference:** check gradient computation (most likely place for bugs)
 - ▶ Is $\sum_s \text{forward}_i(s) \text{backward}_i(s)$ the same for all i ?
 - ▶ Do probabilities normalize correctly + look “reasonable”? (Nearly uniform when untrained, then slowly converging to the right thing)
 - ▶ **Learning:** is the objective going down? Can you fit a small training set?
Are you applying the gradient correctly?
- ▶ If objective is going down but model performance is bad:
 - ▶ **Inference:** check performance if you decode the training set

Structured Perceptron / SVM

Structured Perceptron

- ▶ Structured Perceptron Update:

$$\hat{y} = \operatorname{argmax}_{y \in \mathcal{Y}} w^\top f(x, y) \quad \xleftarrow{\text{Viterbi Algorithm}}$$

$$w = w + f(x, y^*) - f(x, \hat{y})$$

- ▶ Compare to gradient of CRF:

$$\frac{\partial}{\partial w} \mathcal{L}(y^*, \mathbf{x}) = \sum_{i=2}^n f_t(y_{i-1}^*, y_i^*) + \sum_{i=1}^n f_e(y_i^*, i, \mathbf{x})$$

Replaces Expectation
With argmax

$$- \mathbb{E}_y \left[\sum_{i=2}^n f_t(y_{i-1}, y_i) + \sum_{i=1}^n f_e(y_i, i, \mathbf{x}) \right]$$

Structured SVM

- CRF: $\log P(\mathbf{y}|\mathbf{x}) \propto \sum_{i=2}^n w^\top f_t(y_{i-1}, y_i) + \sum_{i=1}^n w^\top f_e(x_i, y_i)$
- We can formulate an SVM using the same features

$$w^\top f(\mathbf{x}, \mathbf{y}) = \sum_{i=2}^n w^\top f_t(y_{i-1}, y_i) + \sum_{i=1}^n w^\top f_e(x_i, y_i)$$

$$\begin{aligned} & \text{Minimize } \lambda \|w\|_2^2 + \sum_{j=1}^m \xi_j \\ \text{s.t. } & \forall j \quad \xi_j \geq 0 \\ & \forall j \forall \mathbf{y} \in \mathcal{Y} \quad w^\top f(\mathbf{x}_j, \mathbf{y}_j^*) \geq w^\top f(\mathbf{x}_j, \mathbf{y}) + \ell(\mathbf{y}, \mathbf{y}_j^*) - \xi_j \end{aligned}$$

- Exponentially large state space! Use Viterbi for loss-augmented decode

NER

NER

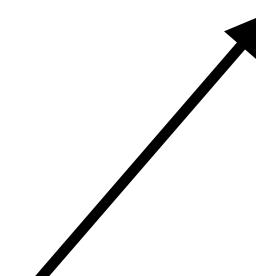

- ▶ CRF with lexical features can get around 85 F1 on this problem
- ▶ Other pieces of information that many systems capture
- ▶ World knowledge:

The delegation met the president at the airport, **Tanjug** said.

Tanjug

From Wikipedia, the free encyclopedia

```
ArrayList<String> list=new ArrayList<String>();
list.add("http://www.google.com");
list.add("http://www.stackoverflow.com");
list.add("http://www.tutorialspoint.com");
list.add("http://localhost:8080/sampleExample/query");
exchange.getOut().setHeader("endpoints",list);
```

and, inside camel route i want to iterate through this

Variable_Name
list

File_Type	Version	Language																				
Website	File_Name																					
Operating_System		User_Name																				

NER in StackOverflow

Two Main Challenges

- (1) **Polysemy** — e.g., “key”, “windows”.
- (2) **Inline code** — code-switch between human and programming languages.

Before adding element to array, check if `key` is numeric is `is_numeric($key)` function. If it return false, then, convert `key` to integer using typecasting, `(int)$key`.

Now, the array will have numeric `keys` only and can be ordered.
